Dec. 5, 1941.

Harold E Edgerton
Dec. 5, 1941.

Spent most of morning yesterday with Bunker, and Schmitt in Biology dept discussing and observing trikosists(?), the barbs that paramecia send out when stimulated.

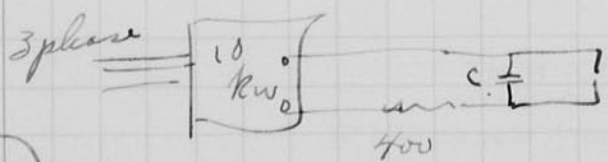
A blue dye was used in the water to excite the action. It also killed the animal but he ejected his darts before passing out.

Then an inductorium was obtained and connected to pass a current through the material with the animals. A single ~~sh~~ shock was ample to excite the action.

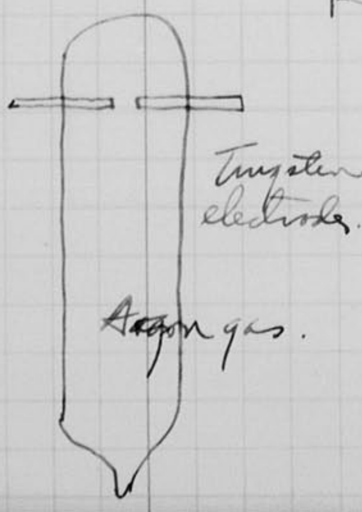
The same experiment was again performed with the geology microscope that had polarizing provisions so that the darts could be easily seen.

The afternoon was spent connecting and experimenting with the movie apparatus so that an attempt to shoot the subject in high-speed could be attempted.

A spark gap was used as before.



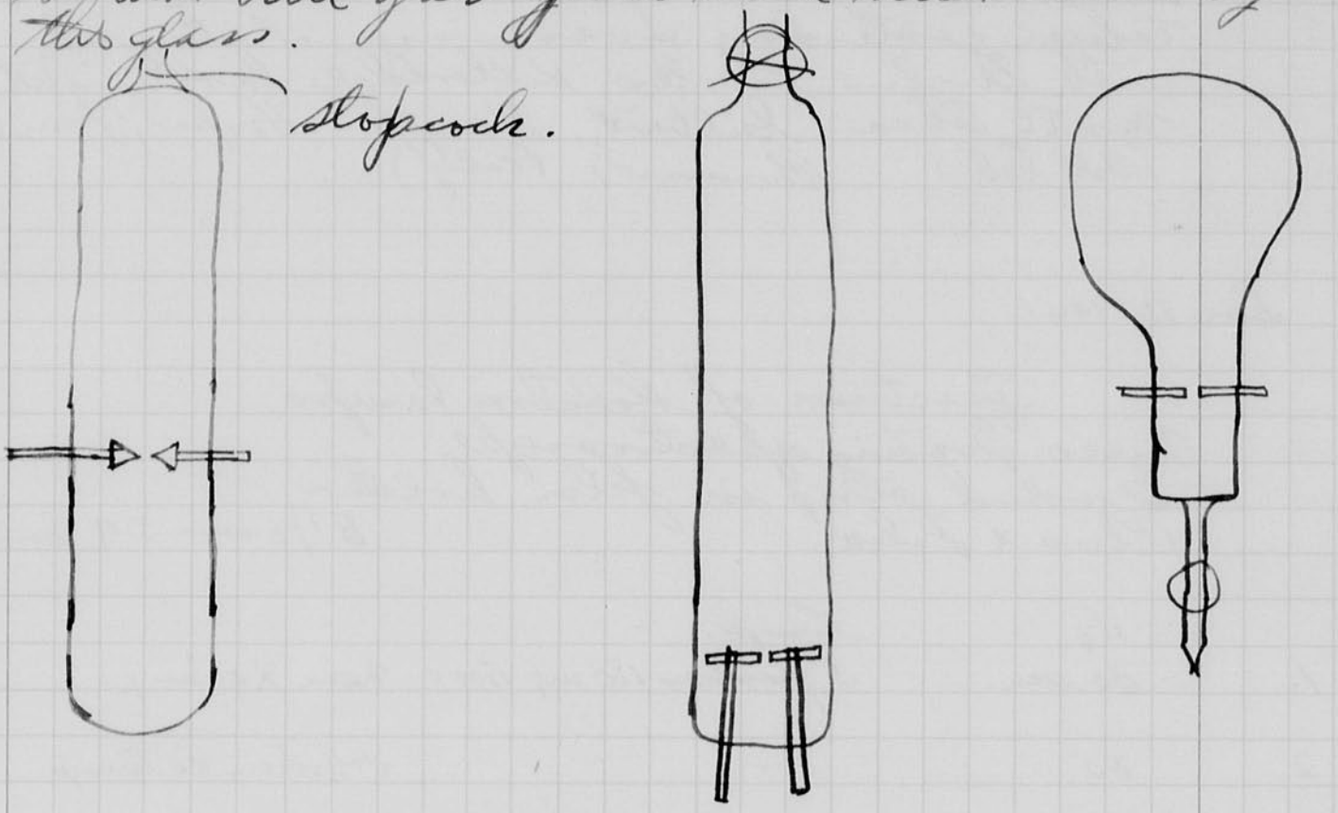
I also tried an argon filled tube that had a 1/2" gap.

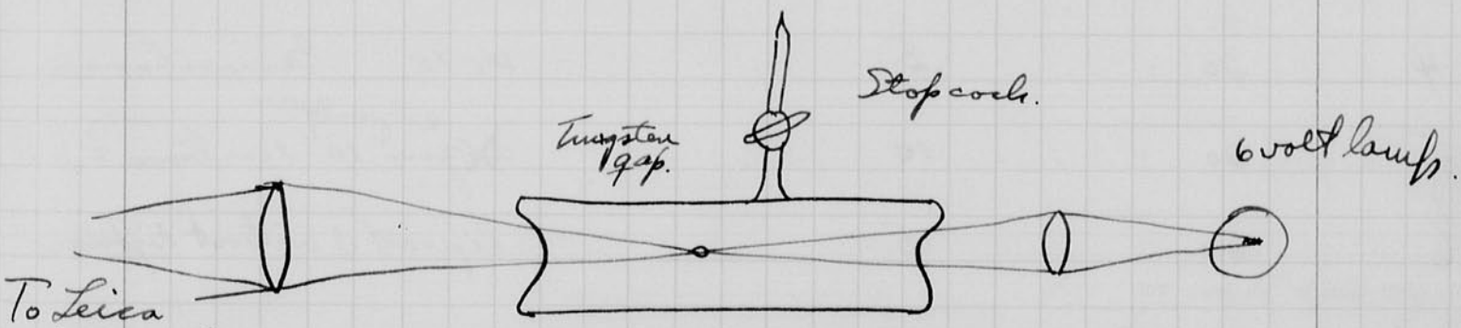


It gave more light than the air gap. I then repumped it after melting the sides and pushing in the electrodes to reduce the gap size. It was filled again to 1 atmosphere.

0.5 mf at 1200 per second was used. Also 2 mf at 600.

The next model will have a stopcock so that it can be run under pressure. Also the gap should be low in the bulb so that the gas flow will heat none of the glass.





Dec 6.

Sat. 4 films taken at 900 frames/sec.
Shock to excite paramecium.
1 mf. 1400 volts neg. Plus x film 100 mag. no eyepiece or lens or polaroid.

Dec. 5, 1941
Harold E. Edgerton.

I returned today from New London where I helped a group from Columbia run at the Sub. Navy yard. Both still and multiflash pictures were taken yesterday evening. I stayed with Gordon Procter Kitteredge last night at Mr. T.E. Shea (Bell lab.) Gilbert, Knapp. (Paramount). Hooper (from Warden, (calif).

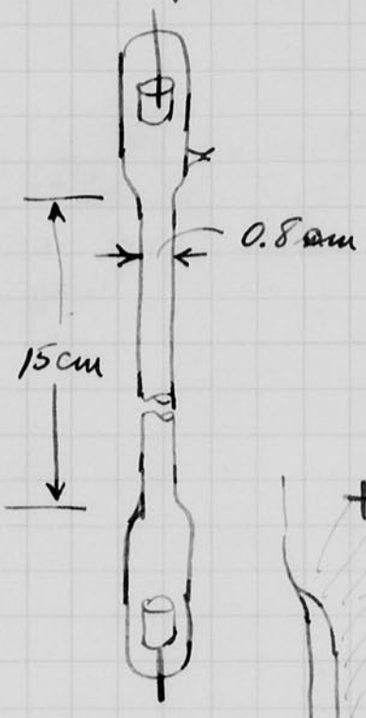
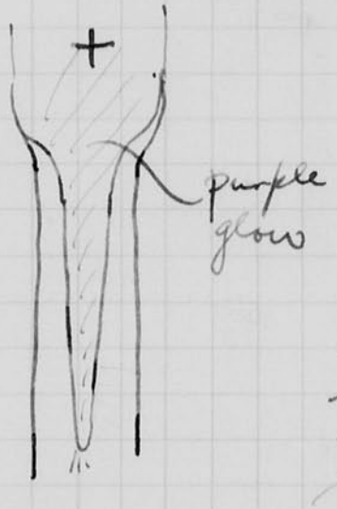
Pumped straight tube and filled with Iodine crystals in vacuum. A double seal off was used.



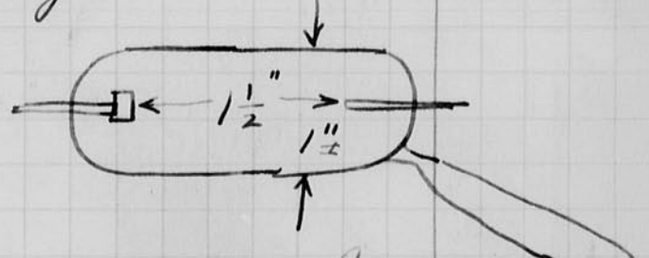
Pointed glow in middle section increased from positive end of tube towards cathode. Condenser discharged when the point reached the other surface of the constriction.



When tube was slightly warm the glow above started about 2000 volts.

The external sparker did not seem to start the tube even if the glow had already started.

A gap tube as sketched below was ~~made~~ pumped and filled with Iodine



Spec 70 to 73 Ions with this tube.

Harold E. Edgerton. Neon.
Wyckoff
Barstow.

A new supply of neon (1 liter) was obtained from "air reduction" and put on the pump yesterday. I also found that the system had a leak. Today I plan to repeat spectrograms for neon gas. The oven is now on a standard spiral tube. See page 31 for entries on pump.

Spec No.	Volts	Cap.	Flashes.	Gas.
113.	1800.	180	10	Neon added to 28cm on top of left over of 112. (11⅛" total.)

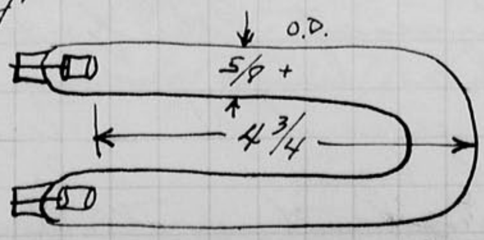
Jan 4 1942

The above tests show that the U tube with 10 cm of Xe is almost as efficient as the standard Xe spiral. However the flash time is less, since the tube makes a distinct click when it flashes. This is due to the high current. It was observed that this U tube did not "craze". A similar tube with argon or krypton would have crazed at 100 mf at 2000 volts.



Pyrex. Cath anode nickel with inside screen Ba.O. paint?

Jan 5 1942 Kenneth J. Germeshausen
Herbert E. Grier

Jan 4 1942 cont
Harold E Edgerton.

Kitredge and Rifkin from A Trumbull New London conn were here yesterday to discuss under water photography and to design lighting equipment, submersible.

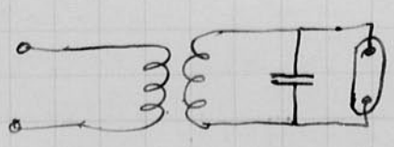
Kit called on the phone several times yesterday to further discuss the possibility of doing the work here in the swiming pool. We also suggested lamp design using a cylinder of lucite or glass for submersion. I required a 3 ft length plus a foot for the control lamp and coil.

I came in last night and tried lamps to see if they would work on the sunie apparatus. A Kr lamp 4 ft long held over even with 1650 ohms at 1 mf. I also tried 3 and 5 mf with better luck. (about 60 cycles.)

Next I made a tube of 17 mm pyrex 3 ft long and filled with 3.2 cm of xenon gas. This gave more light and ran o.k. with 500 ohms and 1 mf.

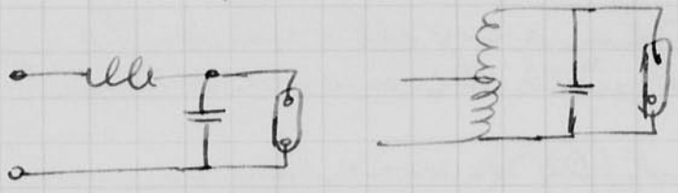
I also tried the U tube (page 36) 19 cm Xe, it had more light than the 3 ft tube. Possibly the 3 ft tube would give more light if the pressure were increased.

I am certain that xenon gas is an efficient medium for the production of photo light from electrical energy. The efficiency increases when the current becomes high. The high pressure is also necessary in the efficient lamp. However when high pressure is used in a tube it becomes difficult to start without the



cont.

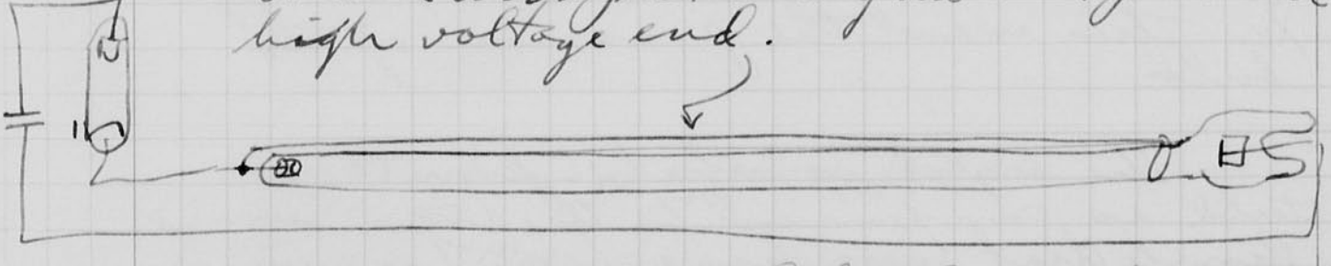
Application of a high voltage or the presence of thermion ionization. The circuit shown on the previous page may have some possibilities. By resonance, the voltage across the condenser builds up to a value when it breaks down the gas. Then the series leakage resistance of the transformer or coil limits the current. By proper balance the tube will go out but be ready for the next half cycle flash



Experiment with movie apparatus - Power supply 866 tubes and relay rack assembly.

Xe tube 3 ft long 17 mm diam 3.2 cm pressure. Some flipping and slight tendency to hold over if resistance less than 1000 ohms with 1 mf.

a wire was put along the tube from the high voltage end.



this helped a great deal in steadying the tube when observing the commutator at 150 and 300 flashes per second. the arc from the cathode to the 1/3 of the anode was against the wire and steady. the rest of the arc was on the opposite side of the tube and erratic in action.

Jan 6 1942

Howard E Edgerton.

Yesterday I pumped several tubes and filled them with xenon gas.

1. 3 ft 15 mm lamps for under water movies. 3 cm xe
2. U tube 14 mm of old type. 4 cm xe
3. 2 movie lamps quartz lined. 4 cm xe.

These tubes were all run on the pump with the movie outfit

I tried the movie lamps at 1, 2, 3, and 4 cm. The light increased with the pressure but some misses were encountered at the 4 cm pressure.

Two "leaker" movie lamps were repaired and pumped with ~~the~~ one of the movie lamps above. all three were filled with 1.9 cm of xe. this was the pressure of the bulb.

The light is white from the xe tube as compared to the argon movie lamp that we have been using up to now. I plan to use these xe movie lamps for all pictures from now on so that their performance can be determined.

Kittredge and Geo arrived at 4 pm from New London. With Jope and Peterson we examined the swimming pool for under water photography.

the long tubes (p 36 37) do not operate satisfactorily. they tend to fire late, also skip, and some holdover.

I repumped one of these today. At lower pressure than 3 cm the operation is improved. However the amount of light seems less. At a mm or so the color is green. I sealed the tube off at 1 cm of Xe from a new bulb.

As I write this two other ~~pump~~ tubes are on the pumps, a movie lamp and a straight tube. The straight lamp is 12± inches long

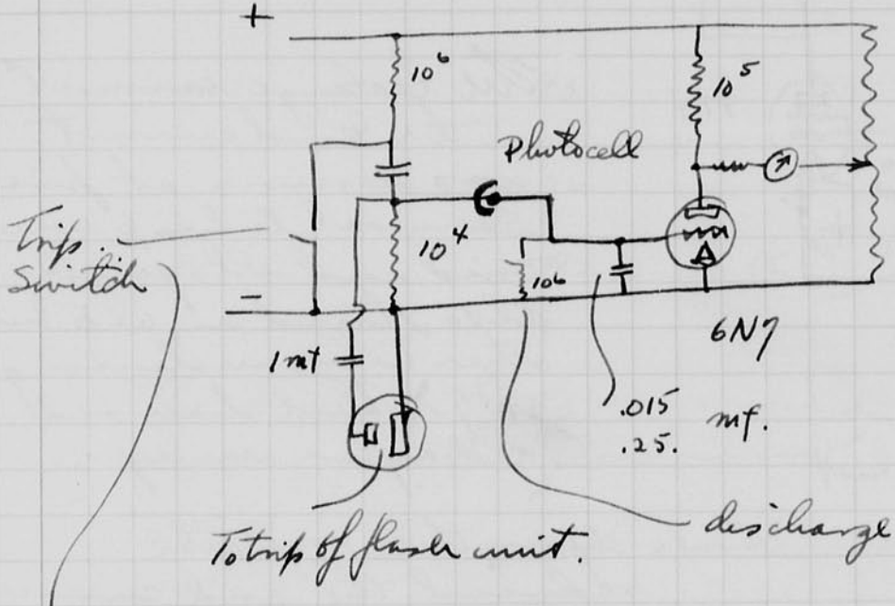
Jan 12 1942

Harold E Edgerton.

I worked last night with Fred Barstow on a photocell integrator with a vacuum tube to read the amount of light from a flash lamp. We connected up the following circuit for experimentation.



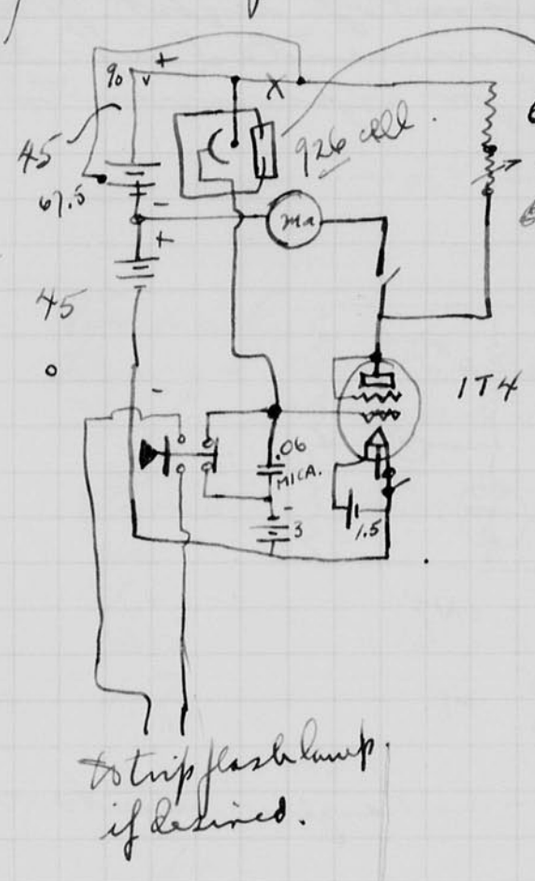
This switch puts potential on the photocell for a 1/100 second at the instant of flash. A circuit was discussed to produce a square wave form for this purpose instead of the exponential one made by the above.

The trip switch caused variable readings on the meter even with the photocell disconnected.!

Jan 15 1942

Harold E. Edgerton. Light Integrating Apparatus.

The following was connected up yesterday with Mr. Grier.



22.5 v / 70,000 = .322 ma.

67.5 − 45 = 22.5

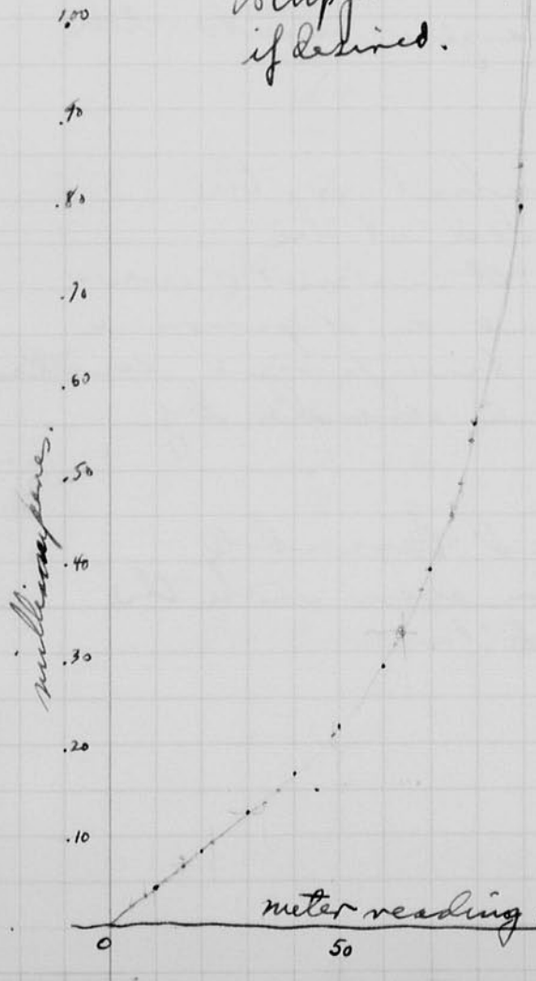
The leakage current in the grid circuit was serious at first. Several tubes, 6, were tried and all equally bad. Also I tried a 6C6 and other tubes including the 6N7 that I used a day or so ago.

Aging the 1T4 tube reduced the grid current. Data as follows shows this effect

$E_g = E_p = 67.5$

Time.	Elapsed time to swing from 0 to 80 ma.
4.	12 sec
5.20	23 sec
5 55	28
6 10	44 after use and tests
6 45	36 after zero bias
6 55	60 " use.

all with .015 mf in grid.



The grid capacity was increased to .06 mica so that grid current would not cause swing. Also plate current reduced to 45 volts as shown above.

Jan. 23. 1942.

Kittredge, Gilbert, Knapp, and others from New London, & Trumbull, arrived at 12 pm on monday Jan 17. We set up apparatus in the swimming pool that night and worked till morning. On Jan 18 night we also worked all night, taking in all 50 movie shots at 200 per second. Plus x film f 2. two lamps Xe 1 cm pressure (dimensions page 50) 3.5 mf 1000 ohms on new movie outfit. Lamps about 4-8 ft from subject. The action was 30 ft from the camera in the port hole in the wall of the pool.

The prints were finished yesterday and sent to New London on the 9 pm train.

Feb 2 1942

Sulfur. 0.1 mm
4 mm tube.

On Jan 23 and 24? Chas Wyckoff and I worked all night taking more high-speed movies of objects in the MIT pool for Columbia University. The negatives were developed by Brewster at Harvard and printed on 16 mm film. These were sent to New London on the 4 oclock train on Monday Jan 26.

I left by car on the 26 at 5 pm for a trip south. I reached the Ymca on 34th st about 12 pm and stayed there that night. At 11 in the morning I gave a talk on stroboscopic light at the Amer Nat Hist Museum. Dr. Lutz. Mili was there. We then left for the mus of mod art and saw Mili's dance photo exhibit. I then left by car for Phil arriving about 4.30. Went immediately to the Frankfort arsenal to see Col Kirk, F.E. Myers, Capt. M.B. Chatfield.

K.W. Beattie. Bald Loco. Eddystone Pa.

A talk was given that night at the Engineers club to the A.S.M.E. I stayed with Mr. Peters in a northern suburb that night.

In the morning I went to Ft Monmouth ~~near~~ Red Bank. ~~at New Lon~~ Col Gillette was there in charge of the educational movies. I met Col. Shaw. Levensen (Warner Bros. sound). Sloan (a Hollywood director) Kinsbeart & Hutchins former students. McDougal Lt. very much interested in single flash photography. Smith. animation. Putnam - asst to Gillette. Dick Sears - movie Pathe.

I left for Washington about 5 pm. Spent night at New Castle. Arrived about noon at Wash and went directly to the Potomac Power Co. Fred Willcutt saw me and arranged everything for the meeting of the A.I.E.E. that night. Had lunch with Welch Pogue my brother in law who now is chairman of the Civil Aeronautic Authority then went to see Admiral Furer who had sent a message yesterday to H. Norwood. He was not there but ~~Mr.~~ Comd. Sylvester and H. Rouse saw me. From their discussion I assumed that the navy was not interested in knowing more about the recognition signal method for air craft using our lamps. I did talk to Mr. Piggot about the under-water photography ~~that~~ Mr. Ewing at Woods Hole is trying.

I then had a short visit with Major Le Man at the signal corp. I tried to see Col. Schosberg but was unable to make an appointment.

Next I went to the C.A.A. and ~~saw~~ Pearson and Metcalf about the beacon flasher experiments. Their reports ~~[illegible]~~ that the lamps did not have a life of more than a few hours.

After the A.I.E.E. meeting I left at once for Boston after staying all night with Margaret. Arrived home ~~[illegible]~~ night at 10.30 Jan. 30.

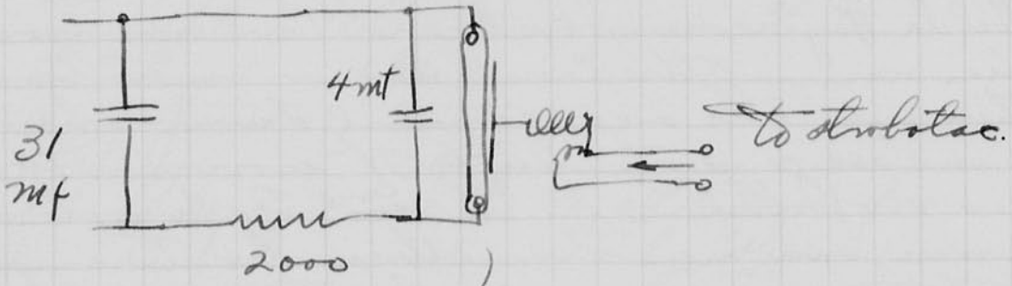
A call was put in to Kittredge concerning more under water photography with more lamps. He wanted to shoot Monday night. I told him that this was almost impossible. He called again the next day suggesting Wednesday night.

On this trip I went by auto. I took the battery operated portable, a [illegible], a photo all [illegible], the multiflash, the microsecond, and a strobotac.

Feb 2 1947
Harold E Edgerton.

Stroboscope lamp.

Herb and I set up the following among other tests.



4 cm Xe gas.
See page 50
12" long. 13.5 mm I.D.

This has occasional tendency to hold over when run long at that the cathode is hot. Will run up to 100± cycles per second.

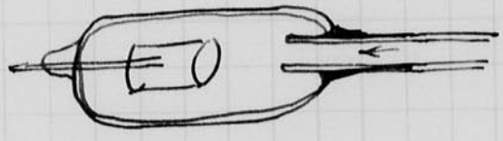
The flash time is about 1/20,000 sec 50 microseconds.

After 1 hour of the above there was a slight discoloration of the cathode end of the tube. The useful life would therefore be some 10 hours ±.

Feb 3 1942
Fred E Eggerton.

Apparently for an discharge, a cathode is needed which is large so that it does not get hot. An easy emitter surface is a help as it lowers the cathode drop and keeps the cathode from heating.

Sputtering of the cathode can be controlled by the use of a re entrant structure such as used on the strobolux lamps.



the glass tube can fit down into the cathode cylinder as in the strobolux lamps.

When the discharge occurs the gas in the tube expands, blowing the sputtered metal towards the back end of the lamp where it does no harm.

Dr Sperback.
Ann Arbor Mich.

Quartz tube 35 mm long.

24.0

Jack Reilly and I worked last night on the exposure meter which was used here. the capacity was changed to .102 mf on the 10× scale which was used for here on. the ×1 scale uses a condenser of .0102±. Both of these condensers are mica. the paper and oil condensers show an objectional drift of some 10 or 15 % in the first second after the meter comes up. Some go fast some —.

note that P.C. now has an integrator and condenser in 0.84 mf grid in place of 0.6 that has been used in all tests up to now.

Feb 22 1942
HEE.

I was in New York on Sat with Drs Kruse, Tisdale, Stiel, McCreary and Mr. Pearce. All but the first is in the C.R.A.F. Borrowed unity flash unit for color photography of eyes at Bellevue Hosp.

Tested exposure meter with mercury arc unit. With 90 volts on photocell - reading 3.8 to 4 which then crawled up to 5.5 or 6.

With 45 volts the reading was less 2.5 to 3.5 which also crawled up about the same percentage.

Also tried the same experiment with the Kodatron type of lamp at 56 mf 2000 volts. Results in table on next page

AR	3.6	3.95
Ne.	1.8	1.95.

this shows that space charge in the photocell is one of the limiting factors, the photo cell voltage should be increased until the readings are constant for further increase.

this was found to be due to an exhausted bias ~~battery~~ battery that was momentarily polarized by the large peak currents

I do not understand why the photo cell should give a gradual increase for a few seconds when the short flash microsecond unit is used

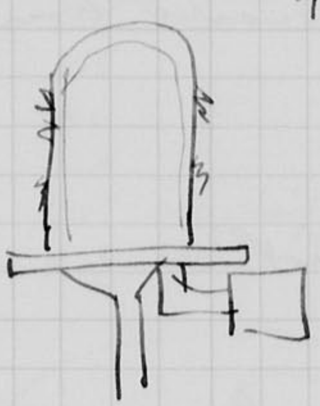
Tubes and holder for army beacon received from Sorstang by air express today.



I pumped a tube with 6 cm Xe of the standard spiral type. the anode end was changed so that it would fit the holder. the socket plug was eliminated.

By accident I first connected the lamp with the anode or tungsten wire to the negative. after 5 min at 60 per min there was darkening at this end of the tube. In 5 minutes the tube was failing to ignite 60 mf 1900 volts 1 per sec.

Polarity changed. then tube held over with 500 ohms in the charging circuit. 2-866A tubes direct from a transformer. added 2000 ohms. Ran about 3 minutes before skipping began again.

Out to supper 3/4 hour ±. tube and socket cooled

Started with a thermocouple under the glass about 1 inch from anode. Lamp skips probably due to impurities and temp. A towel was wrapped around the words between the bulb and the socket.

David E. Epstein

Considerable effort was expended last week in an attempt to improve the operation of the movie apparatus for under water photography of projectile.

Straight tubes were finally used 9 3/4" long 1.6 cm. O.D. 1.3 I.D.

Hydrogen gas was used to assist the deionization and to eliminate the after glow. The tubes as finally used were filled with

Hydrogen 1 to 1 3/4 mm ~~of gas~~

Xenon to 2 to 2.1 cm. of Hg.

Four lamps were operated from the E.R. units (movie). One of these was the one ~~from~~ that is to go to the model basin at Carderock.

Mr. Kaye of the model Basin was here Thurs, Fri, Sat. and Sunday and worked with us. We set the apparatus up in the pool on Sunday night and took trial photographs. See Chas Wyckoff's note book for details.

March 17 1942
Harold E. Edgerton

Germeshausen told me today that his experiments with hydrogen filled tubes for the radiation lab. has been successful for thyratrons operating as a pulse generator at 4000 cycles per second. A 50 ohm load is used for these tests. 10,000 ± volts on the plate.

I was present when Mr. Germeshausen made his first tests on oxide coated cathodes with a hydrogen gas filling of the tubes. If the peak current was too great a cathode bright spot would appear on the cathode. This experiment was performed about a month ago.

The application of the hydrogen thyratron, with its ability to successfully carry high peak currents, and rapid deionization time, was discussed this morning with Mr. Germeshausen and Mr. Brier.

I was in Carderock and last week at the Model Basin. I reported to Commander W.P. Roop. A high-speed motion picture apparatus was delivered to them for their problems.

The week before that was mainly spent with the Group from the Columbia University working upon the underwater behavior of objects in the M.I.T. swimming pool.

March 25 1942

Harold E Edgerton.

Attended AIEE talk last night in Walker by Prof Wilbur on the Wind generator 1000 kw near Rutland Vt.

Maxwell Krasno of Electronic labs was here yesterday and the day before. We had a conference on the design of beacon apparatus and other devices utilizing stroboscopic lamps. A series of comments were ~~made~~ noted by Germeshausen of the various items covered.

Of particular interest is the completion of the development of the large beacon for airplane use. The present tubes sputter at the cathode using a moly electrode in a quartz tube. One electrode of thoriated tungsten, scintered, was delivered to Wright field and seems to be operating very satisfactorily.

March 26 1942.

Barstow tested flash unit last night D.I.C. 6016.

Harold E. Edgerton

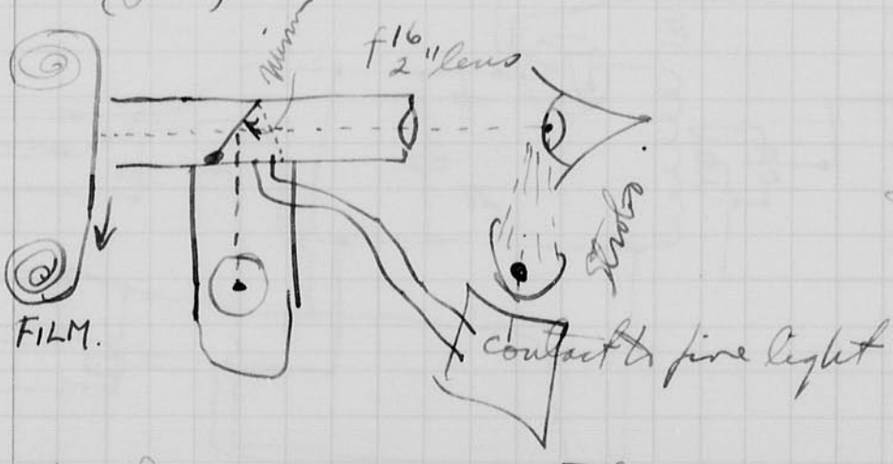
Helped Germeshausen pump quartz spiral beacon lamp for Sonotron Electronics. Tests on the pump were made and are recorded in the data book.

The tube was mounted today in the beacon unit that Electronics sent to us for tests.

It was run for 1 hour with 80 mf at 3 second intervals with a 2nd flash at 1/2 second after the first. No appreciable sputtering was present. Then the capacity was increased to 160 - 240 mf. The lamp held over with 500 flashes changing. Resumed capacity to 160 operation ok. Same operating cycle as before.

Several pictures were taken with Miss Wicks to observe eyes in connection with slit lamp photographs. The photographs show more than the eyes since the depth is greater.



Slide camera back and forth until filament image is on desired spot to photograph.

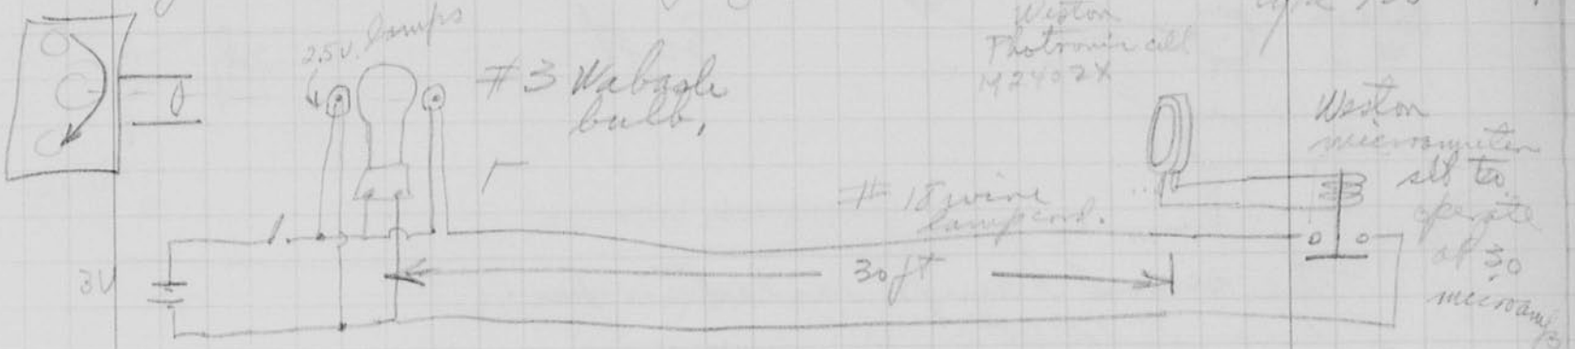
May 3, 1942.

Tests of flash bulb and photocell relay

Yesterday afternoon Jack Reilly helped me set up the circuit below to test the time delay of a flash bulb and relay system.



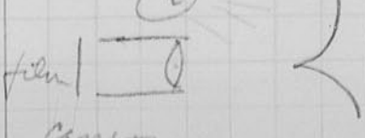
Positive sound recording film used in camera at f 6.3. Bulb (flash) over exposed. The 2.5 V lamps were not bright enough to record. A slow bulb was used for timing. It was too dim to record on the film.

The flash bulb did not operate the relay to flash the second bulb as far as I could see. The contacts of the relay stick in the closed position showing that a contact has been made. They did not stick for this first experiment.

The relay was modified by soldering a small copper wire on the stop so that the circuit was closed when 30 microamps flowed in the circuit. Resistance about 45 ohms in the coil.

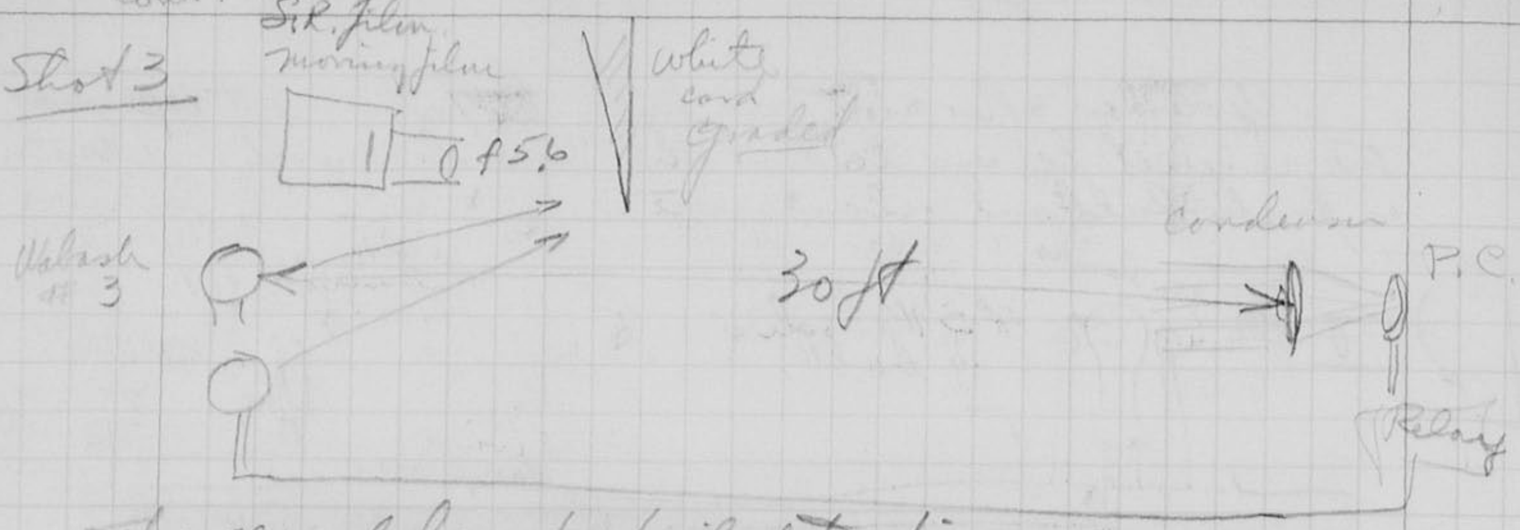
30 microamps corresponds to 40 foot candles on P.C. as measured by a Sek. exposure meter - Photo flood lamp #2.

Second trial. Arranged a 4" condenser to focus the light on the photronic cell. Shot a second flash bulb (#3 Wabash). No operation of the relay by stick test. Used slower camera than above test. A card in front of lens reflected the light.



cont.

Shot 3



the second lamp failed to fire.
Relay did not close the circuit.

Shot 4. Photo cell moved closer (15 ft.)
Shield was necessary to exclude light from window. Camera drop speeded up 85 volts on motor, 60 cycle timer accurately.
~~Shot 4 ft off~~. A wider .459 white card was used as a graded strip. f 2.7 on lens.

Shot 5. Repeat of shot #4 (95 volts on motor)
Aperature f 4
2 Bulbs #3 Wabash
15 ft Photocell to Lamp (flash)
Cell shaded so that ordinary light would not trip relay. (40 ft. candles)

film shows 4/60 sec delay = .066 seconds.

Cathode ray tube.
W.E. 330 C
↑ Blue

Cathode ray circuit.

Some time has been spent the last few days on a suitable cathode-ray sweep circuit for duration and characteristics determination of flash tubes.

The 3 element tube (Western Electric) requires a balanced set of voltages on the sweep for suitable focusing of the spot.

This needs to be linked with the intensity so that the sweep will coincide with the emission of the cathode spots.

June 24 1942
Harold E. Edgerton

Drove to Washington with Jack Reilly on June 7. Reported to Model Basin June 8 for contract services for navy. Wyckoff arrived also from Cleveland.

Worked under Roof until Wed June 17. Don Campbell ensign in charge. See Wyckoff's note book for details of experiments and Model Basin Records.

I left with Richard Pogue on June 17 about 8 pm. Arrived in Bridgeport about 2 pm at auto ordnance plant to work for Ruger. Movies and stills of a machine gun were taken.

Wm. Ruger.

Photo shows arrangement.

Films were taken to N.Y. on Friday June 19 for processing. Deluxe lab. + Shown in Barnum Hotel that night.

Left before 8 June 20 for Boston arrived at 205 School Belmont about 12 noon.

Movie 1/4 mt. Plus X film f 3.2 with diffuser off and hot spot on action. Negs o.k.

Left for N.Y. with continuous motion film camera at 8 am Sunday. Shot dances with Mili in studio at 6 East 23rd N.Y. Home on night train.

cont

In Washington last week I talked to John Burlew about a short flash lamp for very high-velocity bullets. It was suggested that one be developed for bullet photography.

Energy now in flash is $\frac{CE^2}{2} = \frac{1}{3}\frac{7000^2 \times 10^{-6}}{2} = 8.19$ joules

this is enough to photograph at f 8 on fast film under.

If voltage is increased 3 times to 21,000 volts then the capacity can be 1/9 of this value or $\frac{1}{27}$ mf or 0.037 mf.

The discharge time could then be about 1/10 of its present value.

afterglow is responsible for most of the ~~afterglow~~ smear or trailer that is shown. See below photograph.

$\frac{4400 \times 12}{10^6} = .0528$ inches motion in 1 micro second

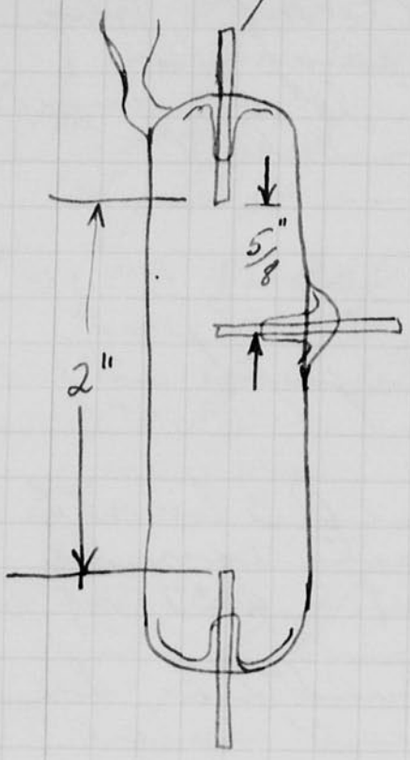
Micro-Flash Photograph of 37 M/M, Special Proof Slug. By: Edgerton Photograph #11

Taken at Aberdeen maryland.

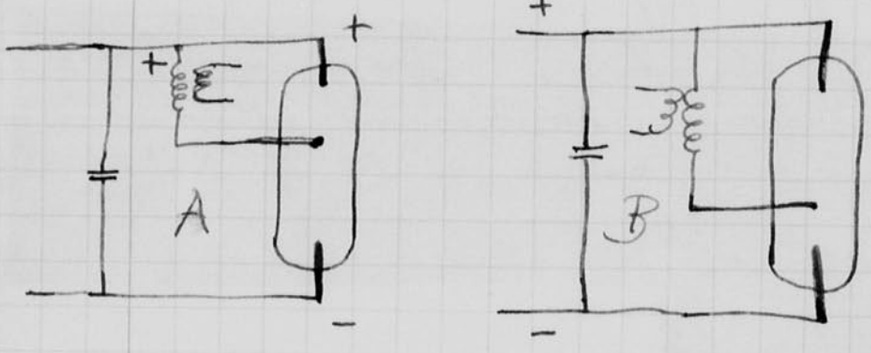
June 25 1942

Harold E Edgerton



Filled with argon tank. 27½ cm.

Flashed with 125 mf 2160 volts.



When tube begins to flash hand the spark coil may shunt through to the condenser negative terminal.

With 3rd electrode starter — the pressure could be
15 cm with connection A.
or 30 " " " B.

With an external wire starter the pressure could be 40 or 50 cm.

Sealed off a second tube with 25 cm argon. Mounted in a Glass projecting bulb with a 5 prong giant base. This tube put on life test with 56 mf

at 4:20 P.M. 2 flashes per minute.

Increased cap. to 112 at 4.42 tube blew up on second flash.

Slight discoloration at ends of tube with 4 flashes at 56 mf.

There was no cable length between the condensers and the lamps for the above test, as there will be with the ~~rotation~~ unit.

Ennis will make two more tubes tomorrow.

40 mil tungsten wire were used for seals and electrodes. the anode gets much more damage than the cathode. I believe the anode end melts slightly with 112 mf at 2000 volts.

no starting electrode

July 6 1942
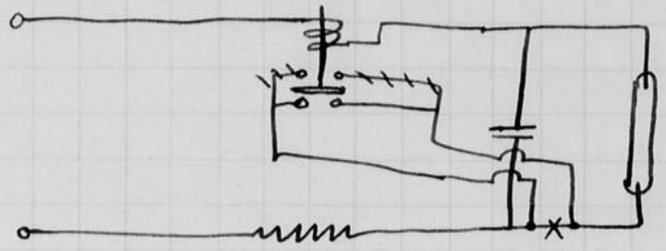
H. E. Edgerton.

During the past week Grier, Barstow, Wyckoff and Germeshausen have been trying out the D.I.C. 6016 air corp flash unit which is pictured on pages 124-127 inc.

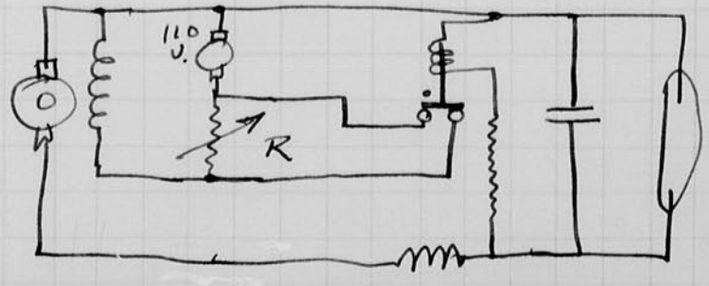
To overcome holdover a relay in the discharge current was used as shown below.



The delay of the relay was to keep the contacts in touch until the current in the discharge path had dropped to the steady state value.

Some sparking was experienced but not serious. An incandescent bulb was put across the coil of the relay to delay the operation.

On July 7 the following circuit was considered while discussing the problem. A relay in the bleeder circuit across the condenser is arranged to open the field circuit momentarily and thereby reduce the tube current. The resistance R shown below is adjusted until operation is satisfactory.



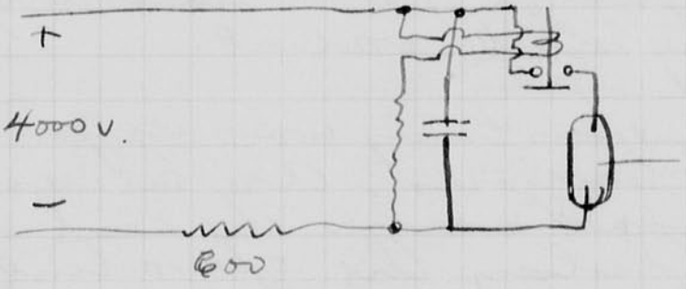
Several modifications were discussed at length today with Grier and

cont

Berglow. Several Relays have been found that have almost the desired characteristics. Tonight as I write this they are connecting up the unit for trial.

Grier is fearful that the charging time of the condensers is going to be too long. He was in favor of going for rapid with the relay in the main circuit. If the field arrangement cannot be made to work then the other will be perfected over our previous efforts.

A positive pull in should be used for this duvet relay.



July 7 1942

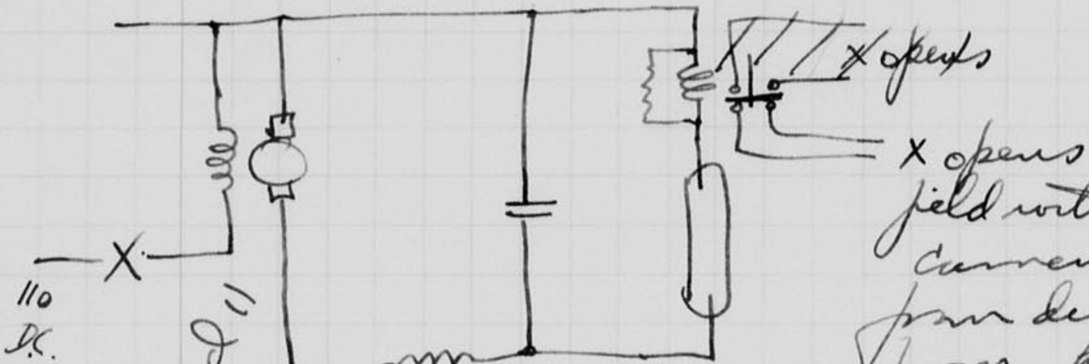
JULY 5 1942 H.E. EDGERTON

July 11 1942
Harold E Edgerton.

Considerable effort was spent the past week by Barstow and Grier on the protection problem for the large D.I.C. 6016 flasher. (See page 129).

A conference with Dick Taylor on the 9 or 10 brought out the following design using a re built automatic electric relay.



field with pulse of current in relay from discharge or from hold over.

Coil specs. 70 turns #14 copper wire resistance 0.03 ohms. Pull in current 3.4 amps. Drop out current 1.7 ..

Copper slug covers half of volume to give a delay in opening - estimated ~~at~~ 0.1 or 0.2 seconds.

Shunt across coil ~~0.06~~ 0.1 ohms.

Two relays will be used - one in each lamp discharge circuit. The control circuit will be in series with the contacts of both relays.

This scheme was tried July 10 and 11 with 2 lamps one of which misfired on occasion. All the lamps were protected very satisfactorily.

Sat July 18 - Watertown arsenal taking pictures with micro second unit of 37 m m bullets hitting stings and wire. the experiments show that a flash of light is produced when the wire is hit. the flash is of very short duration. this explains the pictures that were taken May 28 at Aberdeen. Capt Mathews.

Sunday July 19 Chas. Wyckoff and Geo. went to Worcester in my car to set up movie camera at Wyman Gordon shop. I worked with Fred Barton on the flasher taking spectrum shots on #136 and plotting graphs out window of 4-111.

Stook the 11 pm train to Worcester and stayed at the Bancroft hotel. Got up at 5.30 to work at the forge shop with Charlie. Returned to Boston at noon.

Freight from Wright field arrived Monday for experiment on the new flasher 400 V 4000 m fd.

July 23 1942 the B2 from Wright field came yesterday about 3. Kenyon Jan cook and Freight were in this morning. Barsley called about noon on the phone before going over to the air field.

Installed 6016 D.C. flasher in B24 on last week end. It was taken to Boston air port on ~~Thursday~~ Wed afternoon and stored in the M.I.T. hangar. The plane came thurs. day and unit fitted. The final trial was made on Saturday; then the unit was taken out and the ~~pile~~ plane left about 5 pm for Chicopee (Westover field). Fred is going in a truck tomorrow morning to Chicopee with the apparatus.

Chas W. Wyckoff and I worked with Columbia Univ group at pool from 6 30 to 4 30 am. We have been assembling and testing lamps for this work for the past 3 weeks ±. A total of 6 lamps were to be used on the tests. However one of them leaked last night and had to be taken out of service.

Harold Edgerton.

Lengthy discussion with Herb Grier and Fred Barston this afternoon concerning new design of photography apparatus for 1500 ft low altitude photography from an A 20 B plane.

There are several possible sources of power.

I. Separate motor (gasoline) generator set. advantages 1 can fit in any A 20 plane without modification
2. Can be operated without operating the engines on the air plane.
3. Field control can be used on the generator for deionizing the tubes.

disadvantages
1. Weight

II. Generator on plane motor
advantages.
1. Light weight.
2. Economical power from main plant.

disadvantages.
1. Will require generator change on the air plane.

2. May require wiring changes to use A.C. generator as standby generator for battery.
