Exposure meter.

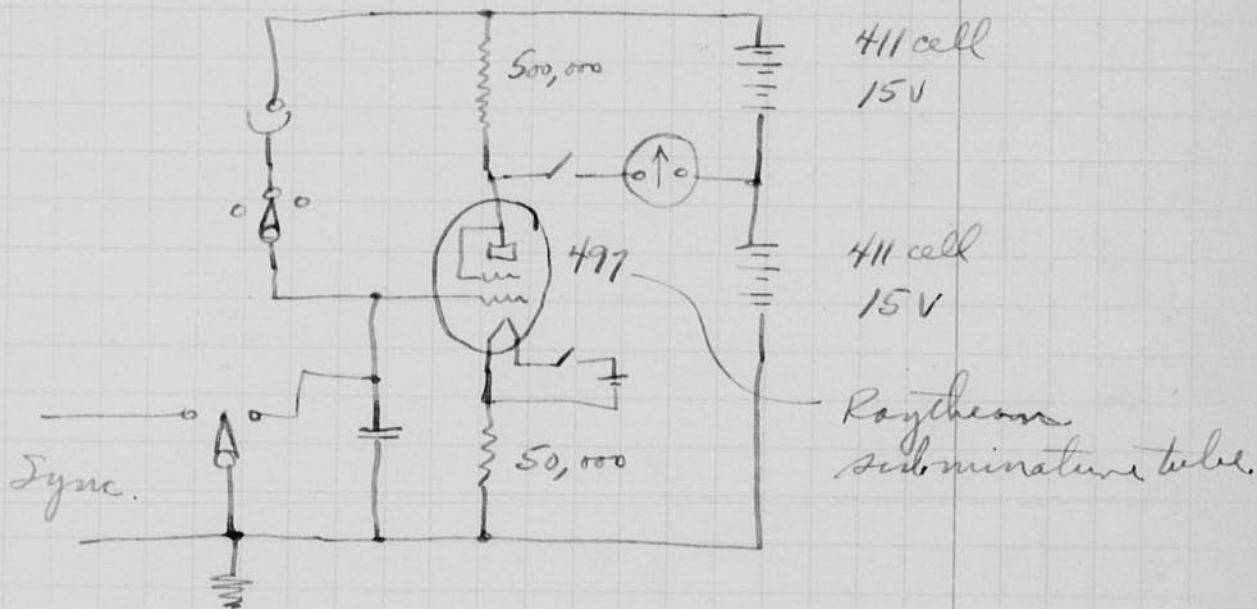

See note book 17 page 139 for design.
It was found that the IP42 phototube was not sensitive enough for some problems.

During my absence at Eniwetok, the Continental Electric Co made the cetron tube no # CE-73V for the end on photo sensitive device. a sketch is shown of this tube.

wire ring anode.

cathode plate with S4 surface.

Edgerton, Germeshausen & Grier (Partnership)

List of Projects

1. Sun Flash
Design completed and 4 sold and delivered. Requires sales effort, completion of drawings and specifications, and new price schedule. Publicity and Sales effort.
2. High-Speed Stroboscope
Prototype completed and tested. Requires completion of drawings, specifications and price schedule. A small amount of additional engineering needed in particular on lamp design.
3. Microscope Illuminator
Bread-board model tested and found reasonably satisfactory. Requires design of a prototype and additional work on the flash lamp.
4. Microsecond Constructed Source
Design on paper and special condensers ordered. Test equipment to determine flash duration required. (photo-cell & scope).
5. Monochromatic Flash Source
Deming's Thesis (Masters, 1948) indicates feasibility of using tube similar to microscope illuminator but different gas filling. Unit not beyond thinking stage.
6. Photo-cell Exposure Meter for Ground Glass Use
Various bread-board models have been constructed. Considerable engineering is required.
7. C.A.A. Illuminator
Report on preliminary tests now in hands of C.A.A. - Design of an illuminator will probably be requested.
8. Air Corps. Night Photography
Wright Field should be contacted, particularly with reference to possibilities of strip illumination.
9. Cloud Chamber Illuminator
Lamp designed. Needs power-pack design.
10. Fundus Camera Illuminator
Microscope Illuminator may serve.
11. Laboratory Illuminator
A general purpose laboratory power-pack is needed for use in cloud chamber work, instrument photography etc. Should cover a range of CE² and frequency.
12. Special Electric Flash and Electronic Devices
These are of a kind devices occur frequently and are handled as they occur.

- 13. Stroboscopes
New Strobotac and Strobolux designs are required for G. R.
- 14. Consulting
This covers Stroboscopes, Electric Flash, Electronic Equipment, Tube Design and High Speed Photography. A number of jobs are active at present.
- 15. Flash Tube Development
This is generally carried out in connection with specific pieces of equipment.
- 16. Electric Flash Equipment Design.
This involves keeping in contact with the field and a continuous development program of improvement.
- 17. Patent Prosecution

Leakage currents of
electrolytic condensers
Springlee 3601 135 mfd 475V.

475V	3 ma
450	2.
450	1.

Power to two capacitors in series

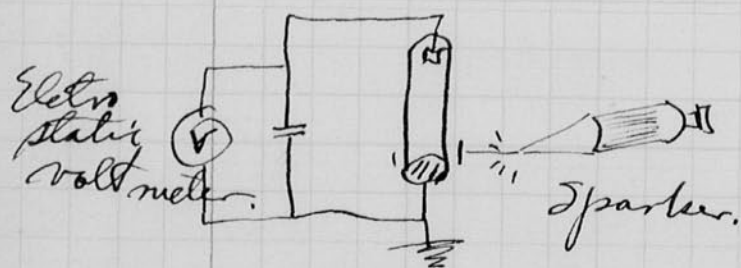

$$475 \times 2 \times .003 = 2.85 \text{ watts.}$$

this is too much for portable design
It probably would be ok for the
1 ma current, that is about 1 watt.

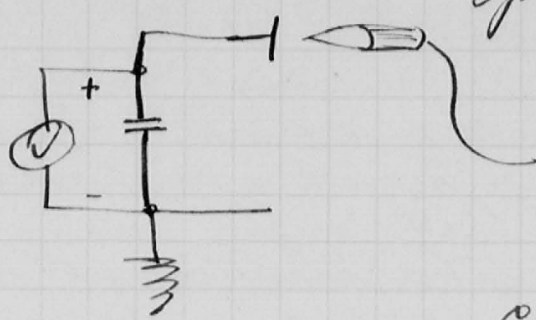

From July 7-11 I was in Los Alamos with
Chas Wyckoff and a group from
the Naval Research Lab. We discussed
the outcome of the Sandstone tests at
Eniwetok atoll.

July 22. Esther & Mary Lou returned from Mex. on July 20.

July 23. On July 21 Rines and his son Bob came to MIT
to see an experiment with mercury tubes.

a voltage was measured
with the set up shown
with the maximum
occurring when the
band was slightly
above the mercury. It was
found that the voltage rose to 5000 volts \pm when
the sparker was held close to the anode.
It was the next day that I took out the Hg
tube and found that the voltage was the
same as with the tube in. In other words
the tube had nothing to do with the anode
effect observed.
The circuit is then

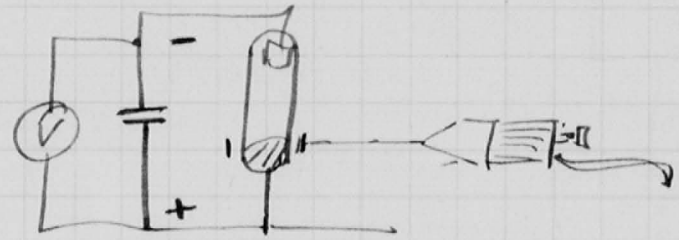

Sparker with $\frac{1}{2}$ to $\frac{3}{4}$ " sparks

The spacing was adjusted so that the sparks would not quite spark.

Corona apparently is needed for the effect to be present.

This apparently is somewhat like the point to plane rectifiers that Bennett was using in Ohio.

Note that the polarity is opposite to that obtained with the band starter.

6 July 23 1948
Harold Edgerton

Some months ago a dry battery portable sometimes called the peanut portable was made using the circuit shown below. This equipment was satisfactory for black & white but only marginal for color. We did take photos of 3 or 4 ft at f 3.5 that were possible for amateur work. The unit was sent to Boon at Eastman and he has it at the present time. An FT-108 tube was used as a source.

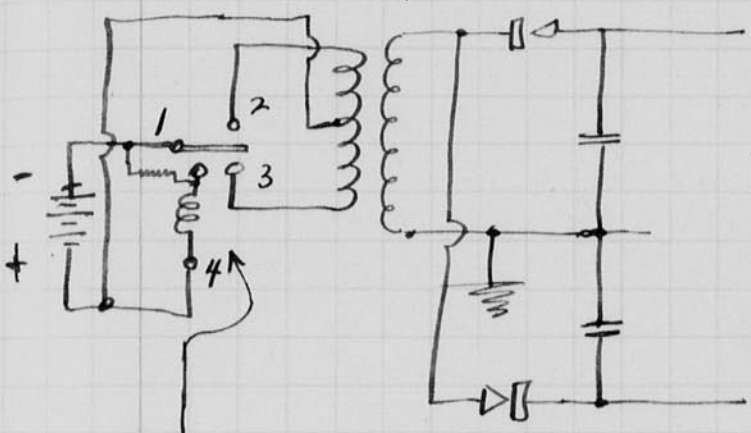

$$R_1 = \frac{1}{2} \text{ meg.}$$

$$R_2 = \frac{1}{2} \times \frac{250}{100} = 1.25 \text{ meg.}$$

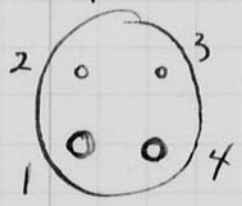

Sync. OA4G trigger tube.

One of the disadvantages of this circuit is the high voltage between the battery and the ground. This is due to the interconnection required by the synchronous vibrator with a common vibrator arm. The synchronous vibrator also is an expensive item.

The following modification may be of interest, since it accomplishes several results, of which the battery-to-ground voltage is one. The extra cost of the selenium rectifiers is partially covered by the saving in the synchronous vibrator. The Aerovox company have sent us some sample vibrators 6V. 250 cycle.

David Egerton

60 cycle
stroboscope
for Stevens
Inst.

Hugh & Seiler from Stevens were here today and designed a flash unit for use in the towing tank at Stevens in Hoboken. Ken Tomeshauser and Fred Barstow were at the conference.

Experiments were made with the old 60 cycle stroboscope. The capacitances are

0.75

2.25

2.85

4.25 mf.

the corresponding voltages are

$$15.7 / 14.3 \times 2230 = 2450 \text{ volts.}$$

$$14.5 = 2260 \text{ "}$$

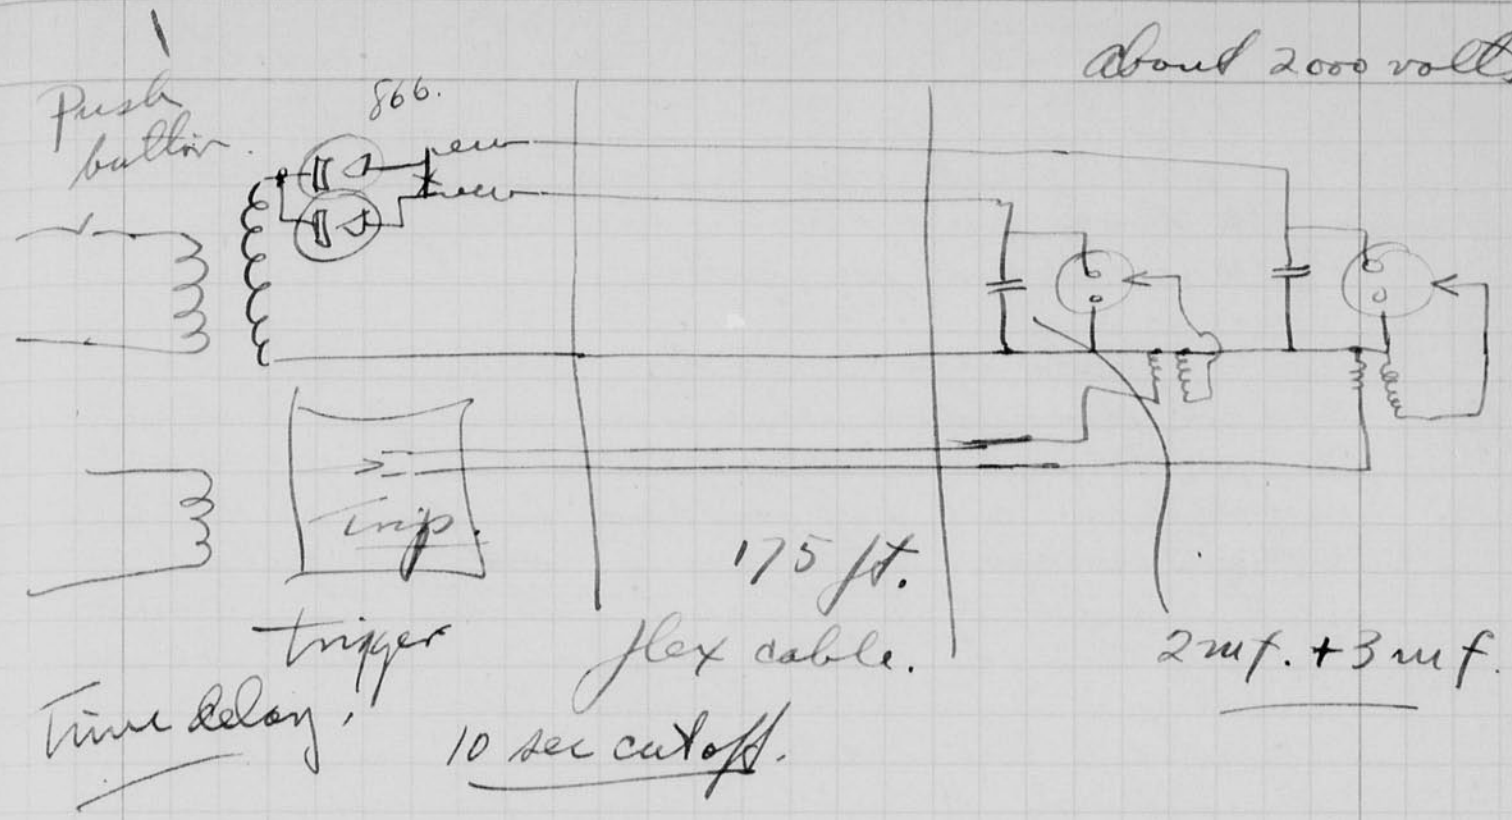

$$13.5 = 2110 \text{ "}$$

$$12.0 = 1870 \text{ "}$$

We connected a FT-220 on the circuit and it operated satisfactorily. Also a quartz FT-24 was tried and was O.K.

We are to estimate on the development and manufacture of a unit to drive two lamps at 60 cycles through a 175 ft cable. The weight at the lamps is to be a minimum. It is proposed that the lamp, spark coil and flash condenser be put on the carriage.

about 2000 volts oper.

August 2, 1948
David Edgerton.

Last week was spent at Lake George with Bob and Bill. We stayed on FORK island site 3.

Tests were made with Eastman Kodak Bantam shutters and SM bulbs. I am trying to show that the synchronizer wire can be adjusted to fire at the maximum opening ~~at~~ instead of at an early stage. With the maximum adjustment, the camera can be used with electric flash. As now made, the camera is not synched for electric flash.

I had a conference with Mentch. Boon, and others, about this, on my last visit. A few SM bulbs were obtained from S.E. to make the tests.

A 929 phototube (5-4) was used to integrate the light from the SM bulb. Between the SM bulb and the diffuser was placed the shutters with the two types of synchronizers.

Light from SM lamp - meter-bulb distance 2.5 ft. atten. at 1.0-meter read 50 lumen sec. per sq. ft. on open flash.
Total light = $2.5^2 \cdot 50 \times 10 = 3125$ lumen sec.

Two tests were made giving 50 and 49 showing that the flash tubes are very consistent. A 1.5 volt battery was used for these tests of the open flash output.

The shutter was now put in position and set for $1/25$ second. It would not fire an SM bulb with 1.5 volts, but ok at 4.5V.

746 battery used. 4.5 volts.

Sarcoid Ejector

The ground glass exposure meter was tested today. I changed the integrating condenser from .001 to .01 mfd.

With the 4x5 camera at $f4.7$ and the E.K. Kodalrm at $8.5 \mu\text{s}$, a white card image produced a reading of about 40.

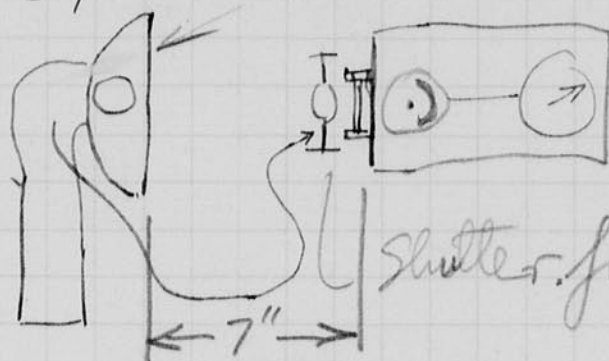

In the photo service studio I found a reading of 25 to 30 for conditions that Judeman uses for his Kodachrome photography. Again a white card was placed at the subject to reflect the light.

Tests were made on a 6 mm OD 4" 25 cm press lamp, today as well as comparison tubes.

Harold Edgerton
Aug. 12, 1948.

Trouble was experienced with the selenium rectifier yesterday and today. One stack opened after the flash lamp was put on. I replaced one plate today and operation was ok for a short time, then the other stack opened and a bad odor was present. Apparently the selenium was being evaporated into the air.

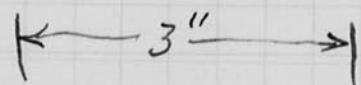

The trouble was probably caused by the unbalance of capacitors, causing an initial reverse charge on one capacitor. This increases the back voltage and probably starts the disintegration of the selenium surface.

For the above I had been using 31 plates in series for a 400 volt output.

I now am using a cased stack with a C.T. which was made by cutting a slot in a standard 2000 volt stack.

Slot with connector to get a mid tap connection.

(31 discs stack 1" long.)

The voltage drops from 800 to 720 with the 3" doubler rectifier shown.

EL 625 transformer P17.

.001 mfd across secondary, gives 670 volts
 with 4 rolls wet storage battery.
 D.C. drain with 90 mfd mellow
 electrolytics (4 in series-parallel)
 90 mfd
 0.34 amps.

I propose to change the primary
 turns from 26 on either side of the C.T.
 to

$$28 \times \frac{1}{800} = 22 \text{ turns,}$$

this will increase the output volts
 and the flux density.

This was accomplished 46 turns C.T.
 with .001 Buffer on 3000 turn coil
 Drain = 0.4 to 0.5 amp from 4 volts -
 Output = 800 volts, D.C. on 90 mfd
 Peak drain = 5 amps from wet bat.
 390 volts

Light output 100 lumen sec sq ft at 1 ft.
 Perpendicular to flat of V tube.

$$\text{Output} = 100 \times 10 \text{ lumens} = 1000.$$

$$\text{Input} = 90 \frac{900^2}{2} = 28,800 \text{ watt sec}$$

$$\frac{1000}{28.8} = 34.7 \text{ lumens/watt}$$

this seems high - the capacity
 probably is more than 90 mfd.

Dry Bat operation 746. (3 F cells in series.)
 4.5 volts

Max current = about 2 amperes
 Final voltage 700 ± 38 volts, 5 amp
 drain.

Aug 17 1948
David Edwards

21

The sockets of the 4 flash units in Photo Service were changed from 5 prong giant to the new 3 prong with a focusing lamp internal socket. New FT-403 tubes were installed. The old FT-2 tubes had been in since 1941 and were still going strong. Judwan noticed a slight increase of light with the new tubes.

I took my small light meter for ground glass meas of light over to the studio and shot two photos with Judwan. He recorded the lamp set up in his note book on color. One photo was taken at a setting of 24 and another at 28. (f11) old Kodachrome film. The film came back yesterday. It was slightly fogged around the edges. Exposures were fair, probably ok. if film was new.

A white card was used to reflect the light into the camera. Then the pickup photo tube was put over this spot. The meter now has an 0.01 mf mica integrating capacitor. Roythem peanut tube. The photo tube is a special one built by ~~in~~ Continental (near Chicago).

Aug 23 1948.

Harold E. Egerton.

I was in New York on Aug 19. The small light meter was taken for test. After meeting Swartz on 44th st at his new establishment, ~~we~~ we went to the Pogano studio and worked with Bluestone on the ground glass problem. Bluestone has an early model of G.R. battery operated exposure meter (light meter 1501) with a 3ft phototube extension and a smaller integrating capacitor. As I recall, the capacity is about 0.013 mfd instead of 0.1!

0.038? My new small meter with the 0.01 mfd capacitor and the end view phototube gives a reading on the ground glass of 25 for Kodachrome and Ektachrome against a white card. This checks with Johnson of Photo Service.

Light level for Kodachrome.

Ground Glass Exp meter.
 \$ m f 2000 volt 220 tube with diffuser.
Output. SR light meter, 1 ft.

Reading (x1) 65 lumen sec. sq. ft.

For reading of 25 on Small hand meter
 as used for Kodachrome tests.

Distance = 15.5 ft.

Light then on ground glass is

$$65 \times \frac{1}{15.5^2} = 0.271 \quad \text{lumen sec. / sq. ft.}$$

the actual light might be slightly more than
 this since the ground glass may
 absorb or diffuse slightly.

Ratio of meter sensitivity = $\frac{65}{0.27} = \frac{15.5^2}{1} = 240$.

for 65 reading \rightarrow 25 on scales.

$$700 \sqrt{65.0}$$

Aug. 27, 1948.

Harold E. Edgerton

I attended the convention of the photographers association in the Stevens Hotel on the 24 and 25th. On the train I met Jim Purcel of Bachrach's studio. He specializes in wedding photographs and was on the way to Chicago to put on a demonstration for the convention. The Bachrach studio was asked to put on the demonstration by the P.A.A. with a \$1,000 fee to cover ~~expenses~~ expenses.

The display booths in the basement were very interesting to me since there were many flash units on display. The Eastman Company had their new model Kodatron unit on the upper floor. Ozyzy Nieziel (?) gave demonstrations of the use of the equipment for Ektachrome. The pictures were excellent.

Photogenic had demonstrations of their equipment next to Eastman. I had a talk with Mr. Kurbiac.

Harry Parker now calls his outfit the American Speedlight Corp. and has big plans for exploitation. There was a 1000 watt second flash unit on display with a single lamp and large reflector. At least two condensers blew during the time I was there. Parker also had some of his smaller units on display including his portable with detachable bottom.

Stroboresearch now has their monostrob unit ready for production. It has 28 mf at 2500 volts (90 watt seconds) in the lamp house. The entire power supply is there. This eliminates the high voltage plug problem. I met Brin and saw Ed Farber.

I met and discussed flash photography with many other people in Chicago.

$$\frac{CE^2}{2} = \frac{54(2400)^2}{2} = 155 \text{ watt seconds}$$

$$RC = 5 \times 54 = 270 \times 10^{-6} = \frac{1}{3000} \text{ sec.}$$

$$Q = 35 \times 155 = 5420 \text{ lumen seconds}$$

$$N \text{ CPS} = \frac{5420}{10} = 542$$

$$U = \frac{542}{d^2} = \frac{542}{4.41} = 125 \text{ ft candle sec.}$$

if effy is 28. then $U = 100 \text{ ft candle sec.}$

I visited Ausco on Sept. 13 (Gilman Morse) a light meter no 113 was left with them for tests with color films. Mary Lou was left at Cornell in Ithaca in the morning. Billy Andrews went with us to Ithaca. Saw Dexters and Mc Shrogs at Cornell.

Ausco tungsten color film with Corov. 12 filter apparently requires a ft-candle sec. exposure of 32.

On the 14th of Sept I was in Rochester where I saw Rupper at the Research Lab about color exposures. He has started work on the color Kodatron and will have data soon. Saw Bob Sandell and Mentelch in the afternoon before leaving for Belmont at 4.30. Arrived 3 pm Sept 15.

On Sept 15 I visited B.R. and obtained the photo cell pickup for the ground glass to fit the 1501 meter. In the aft. I went to Forbes Litho with Barstone to see the photo lith process.

A three way plug (jones) was put in the panel of my exposure meter for the photo cell.

With the Kodatron at 10 ft - camera lens at f 4.7. A white card gave a reading of about 150 on the 1501 meter using the ground glass.

Sept. 24. 1948

David E. Egerton.

I came up with a simple idea today. Why not make an a.c. portable within the camera - light structure. With ac the electrolytic capacitors give us no problem due to their leakage current. With the new V tube we can get at least half the portable light with a 3 pound affair.

Bill and Fred came up with a cylindrical design with a reflector on the side. The camera will attach on a side bracket.

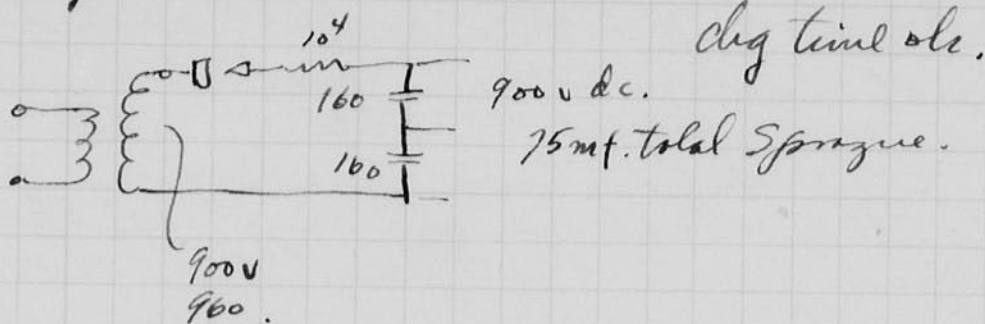

I took Eddie & word over to see Dave Nilsson today. They plan to set up photos of hands in color.

Tanderson of Graflex was here today to see about the McPol work on power supplies.

Dr. Trotter was here today - Eye photographer

could use 35 or 36. ©

This transformer was finished Oct 8 and
tried out.

Input 115 — 900 out dc after
condensers or charged
for an hour or so

at first they charge
up to 780 - 1800 volts
in about 15 seconds.

I believe this design is satisfactory
for final voltage and charging time.

the input final current is about
20 to 40 ma. from the 115 volt
source. this is exciting
current.

the transformer is barely warm
after long operation.

H. S. G.
 Oct 19, 1948.

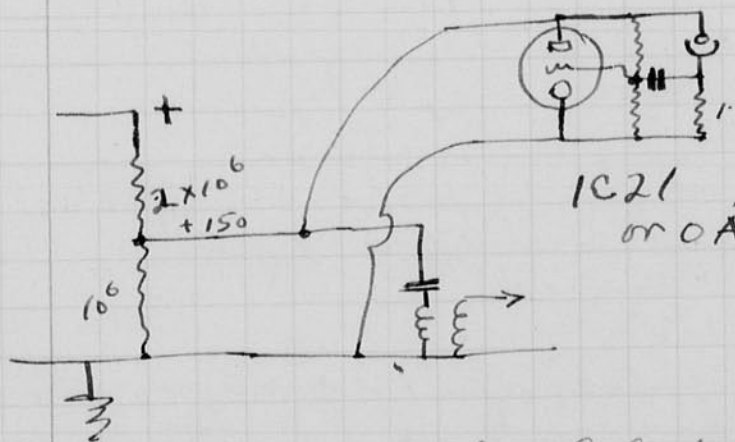

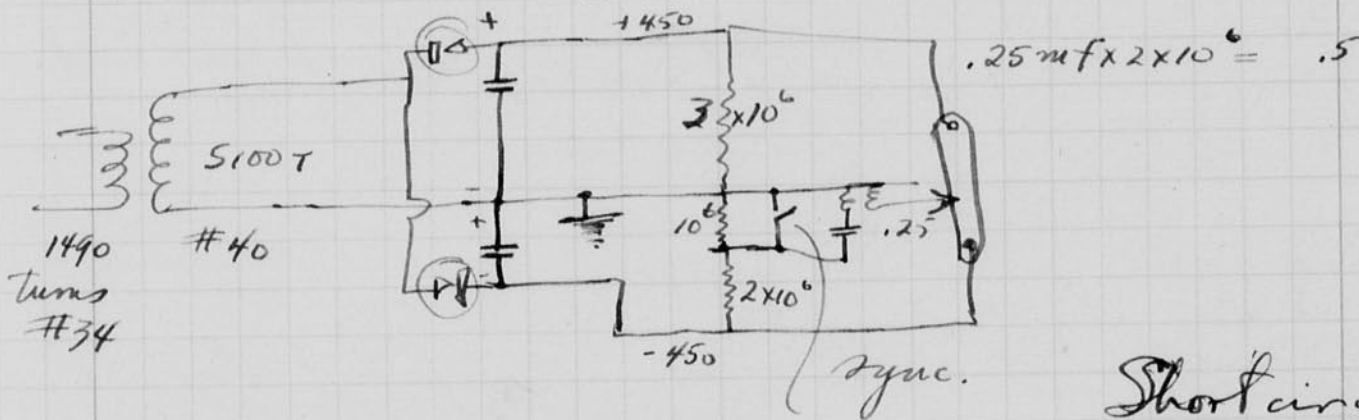

Fred Bastow married Ann Robinson yesterday at the Wayside Inn in Dubuque. I shot Kodachrome at 40 guide factor with the 50 pound trans portable.

Oct 12 1948. Portable design. Conference yesterday with Greenbaum on selenium rectifiers for the project. the cheapest combination at present is eight .65 50 mil stacks (130V each) the cost each is about $\frac{28}{8}$ f.
 2.74

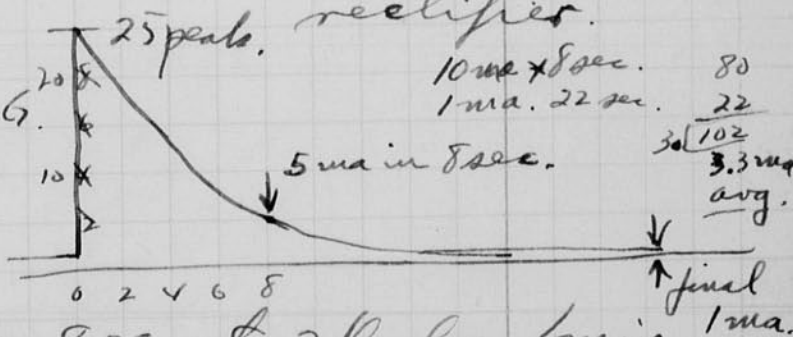

two 1000 volt stacks. were ordered for trial also from A.T.T.

Bastow suggested a contactor trip without a trigger tube. We found that 150 volts with 0.1 pf was marginal.

$$I = \frac{45}{10^6} = .45 \text{ ma.}$$

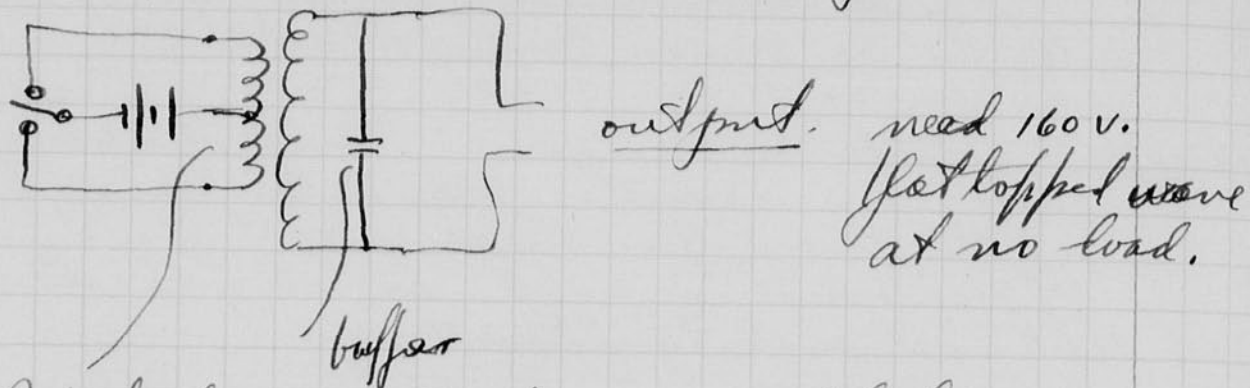

Short circuit current = 25 ma. in Selenium rectifier.

Lamp connected for life tests 8.35 at 2 flashes/min. this lamp has plain tungsten electrodes.

Oct 12 1948
H. S. Egerton
Cont.

Power supply for \$ 110 ac
Camera power supply flash.

Input about 8 volts from 4 volt battery.

$$Ratio = \frac{160}{8} = 20 \text{ with C.T. on low side.}$$

Life test started on
tube with plain
tungsten electrodes
at 1/2 min. int.
interval.
165/2 mf 900 v.
Start 1 pm.

6.3 volt C.T. transformer produces about
120 volts square wave with 0.1 mf.
4 volt wet battery, 1.5 amp drain
when capacitor is fully charged
on flash unit 4 or 5 amp peaks
initially.

Oct 17 1948

David Edgerton Factors influencing Flash Lamp design.

M.I.T.

See J.O.S.A. July 1946
Electronics June 1948.

$$CE^2/2 \text{ energy stored} \times \eta (\text{efficiency}) = \text{Light energy } Q.$$

Type of gas. Xenon seems to give the highest efficiency and best color. Krypton is second best followed by argon.

Pressure. For a given tube the efficiency appears to increase with pressure up to 10 cm or thereabouts.

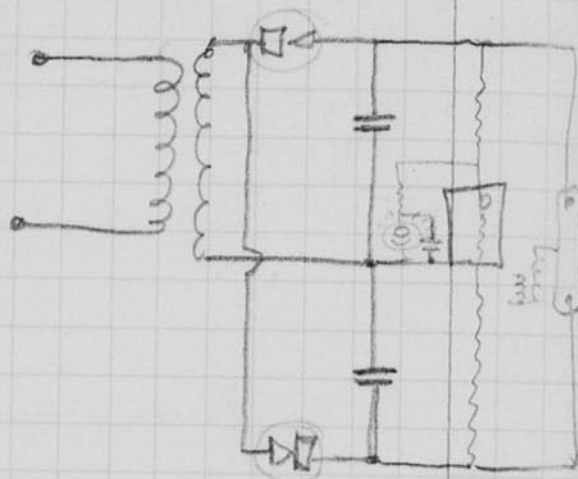

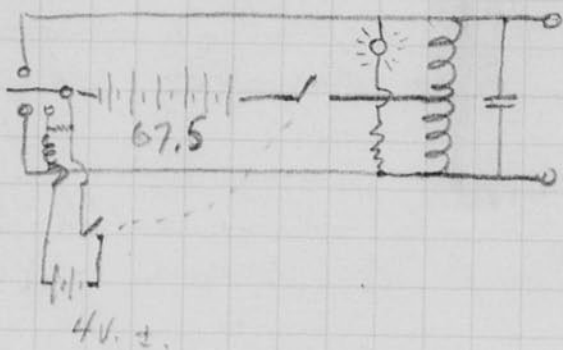

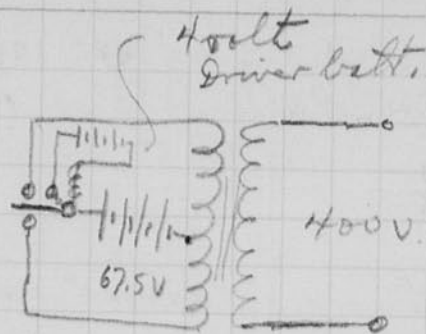

Dimensions Small changes in dimensions apparently do not influence efficiency, ~~but~~ there must be however a tie-in between length, voltage, and pressure. One criteria probably is volts per unit length. Possibly the mean free path should be related to the diameter.

External factors to consider.

- Volt ampere characteristics
- Voltage applied,
- Energy - $CE^2/2$ discharged.
- Final voltage after flash.
- Damage conditions.
- Self start voltage
- Minimum start conditions.
- Color variations
- Time of discharge.

INCIDENT LIGHT
No. 105

The meter is direct reading in lumen-seconds per square foot (approx. 1 lux = 1 ft-cd) with the diffused disc furnished. At otherwise the instrument with the polaroid set on A. The reading on the meter is direct. Without the diffuser the reading should be multiplied by a factor $k = 0.0126$.

From calibrator seconds output of a lux is obtained by multiplying the average in lumen-seconds per square foot by the lux meter distance squared.

High Pressure Light

Source.

Apparently neon gas at 10 or 100 atmospheres pressure is a very efficient converter of energy into light even at low currents. Difficulty is experienced in building such tubes because of danger after the tube is sealed off, the glass is always weak in tension and may go off with explosive force.

I propose that a tube at 1 atmosphere or so pressure be used with precise timing so that the wave is at the center at the moment of capacitor discharge. This operation will be stroboscopic but at a high frequency the frequency will depend upon the sound velocity and dimensions of the glass tube. For this work the tube will probably be spherical in dimensions although a cylindrical form can also be used.

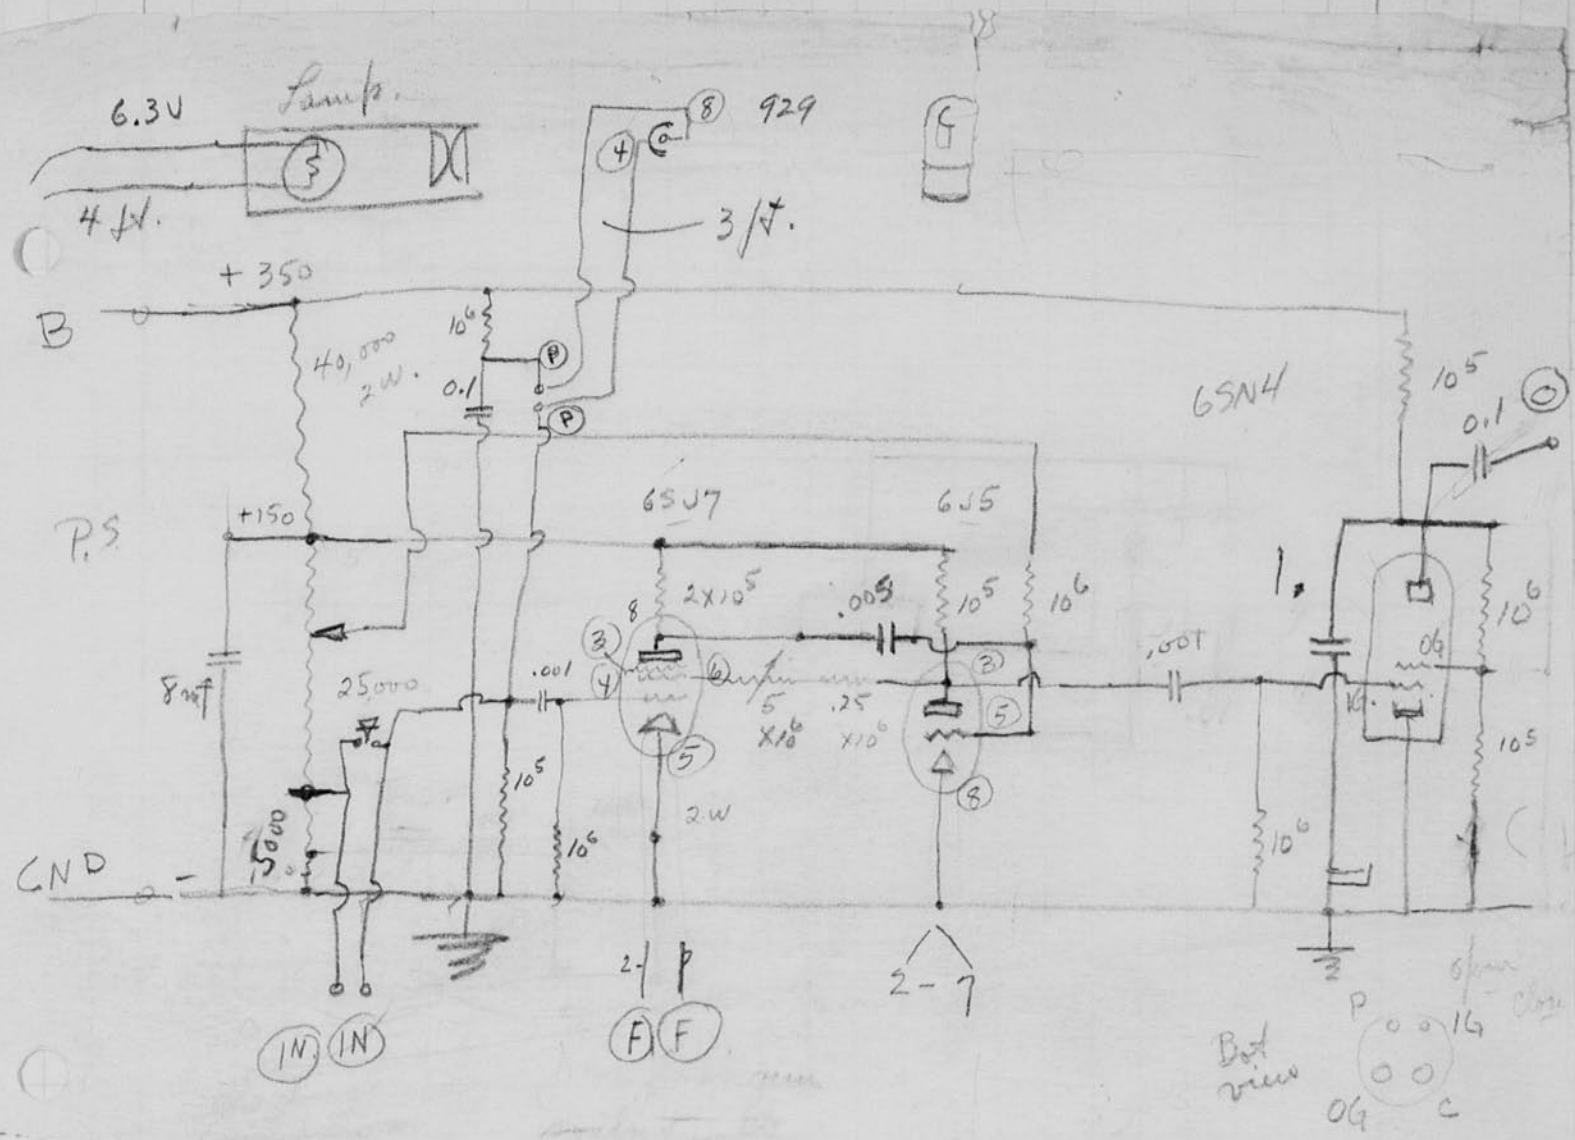

Read & understand
K. L. Semichon
Oct 22, 1948

The first flash will set up a transient pressure wave. When this wave is reflected back onto the center, a second flash will be called for at the moment of high pressure. Subsequent discharges will be timed to correspond to the peak pressure.

Adjustment of the flashing rate will be made until the light output shows a maximum.

Assume sound 1000 ft per sec velocity frequency will be $\frac{1000}{D}$ flashes per second.
 Example $D = \frac{1}{3}$ ft. then $f = 3000$ per second.
 We could use sub-multiple frequencies such as 1500 or .

The lamp caged badly at 1000 V 270 emf.
Efficiency was ok at 900 V after caging
but mechanical failure resulted from
caging cracks

Thus limit is about 100 watt seconds at 900 volt level.
Is caging an area or volume phenomena?

Spragze
270 mf 985V
weigh 2# 10oz.
in 6 cans
1 3/4" diam
3 1/2" long

Surface = $3 \times 2.54 \times \frac{3.4}{10} \pi = 8.14 \text{ sq cm.}$

Radius π $\frac{.06}{.36}$

cubic volume of tube = $3 \times 2.54 \times \left(\frac{3.4}{20}\right) \times \frac{\pi}{4} = 0.69 \text{ cubic cm.}$

Cragging
limit assuming
volume

energy = 100 watt sec.
Volume = 0.69 cc.

energy = 145 watt sec/cc.

Design lamps for $270 \times 3 = 510 \text{ mf at } 900 \text{ volts.}$

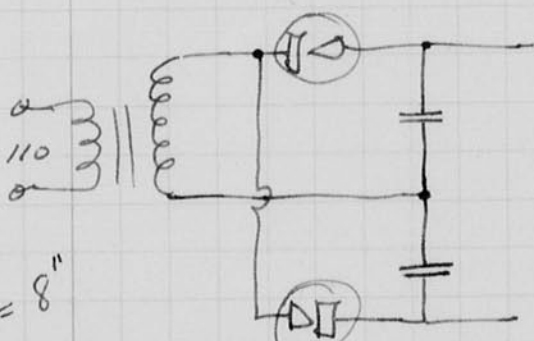

Watt sec = 327 rated.

actual = ?

diam of tube for 145 watt/sec/cc limit should be

$3.4 \text{ mm} \times \sqrt{3} = 5.9 \text{ mm length } 3."$

24 plates

Ratio = 3.57 pr to sec.

A study has been made of the use of flash lights in the Boston Garden for hockey photography. I plan an installation of eight lights with synchronizer cables lead to the press boxes. 18" Reflectors with a 15 or 20 degree beam will be used so that the lights can be a long ways off.

Dec. 1, 1948.

Harold Edgerton.

A sphere lamp is to be made at
 nela for the pulsating-pressure lamp.
 Today I sent a final request for a
 1 cm gap in Krypton or Xenon at
 1 atmosphere.

The frequency will depend upon
 the dimensions of the sphere.

let v = velocity of sound in
 Xenon at 1 atmosphere.
 (approx value).

$$f = \frac{2R}{\lambda} = \frac{v}{2R}$$

I propose to pulse the lamp at
 a variable frequency near the
 resonance frequency of the gas pressure
 wave so that a measurement of the
 efficiency increase can be measured.

Bird and Niehe came in today to
 discuss their thesis on the effects of
 dimensions on the efficiency of a flash
 lamp under different conditions.

- Factors are
1. Tube length
 2. Tube diameter
 3. Voltage
 4. Capacity.
 5. Energy per c.c.
 6. Energy per sq. cm.
 7. Gas type. (Xenon)
 8. Pressure > 10 cm.

Also discussed thesis work with
 Smith and Witter. One proposal was to
 measure the efficiency curve of the
 FT-617 flash tube in an effort to
 finish up the work of Ben Logan.

Die-cast aluminum socket housing, aluminum joint fastener.

Heavy-duty porcelain-shell mogul socket keeps lamp in fixed focus. Includes lamp grip.

Combination water-resisting and cable-securing gland.

4-foot cable (2 conductor No. 12) for convenient wiring.

Strong galvanized steel trussion bracket provides for rotation through 240 degrees vertical, 360 degrees horizontal.

Asbestos-treated gasket makes heat-proof, watertight joint.

Fig. 1

High efficiency, long-life reflector—Alzak finished aluminum, polished for narrow beam, etched for wide beam.

Wear and weather-resisting welded locking handle for convenient one-side clamping.

Degree scale and repositioning stop.

Single extruded gasket completely surrounds door glass edge and ensures a weatherproof seal.

Hinged door swings down for easy servicing.

Flat base fits directly on all other mountings shown.

1. Factor "F" shows distance from projector to surface lighted, gives approximate diameter of beam within.
2. For smaller lamps, reduce lumens and candlepower values approximately in proportion to lamp wattage.
3. When door glass is omitted, lumens and candlepower values will be increased initially by 5 to 10 per cent.

REPOSITIONING STOP CAT. NO. 3552519P1

Both vertical and horizontal trunnions are equipped with repositioning stops. This stop, of die-cast aluminum, fits over the degree-scale and locks into position with a set screw. This stop facilitates resetting if floodlight is rotated for servicing.

Locking handle permits one side clamping and eliminates necessity for using wrenches in making adjustments.

Harold Edgerton

Al Groves and Herb Miller were here from Los Alamos today. Inspected the new Bldg on Huntington Ave.

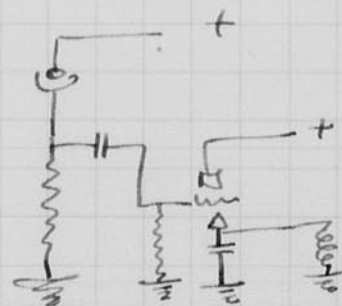

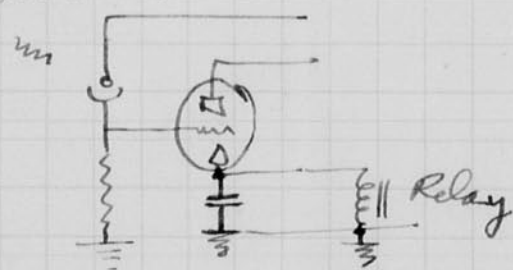

Alfred Andrews of Industrial Electronics Co was here today with a Burglar Alarm System. Barstow, Gernsmauser and Mc Roberts tried a 60 cycle strobotron with some success.

Pickup circuit suggested for strobotron:

Andrews took this with him.

Could use:

High peak light through the use of a cathode follower charges a capacitor that holds the relay in a closed position. Dropoff of the light causes the relay to drop.

with a $\frac{1}{8}$ " hole the velocity is dropped to 100 ft/sec.

March 16, 1949

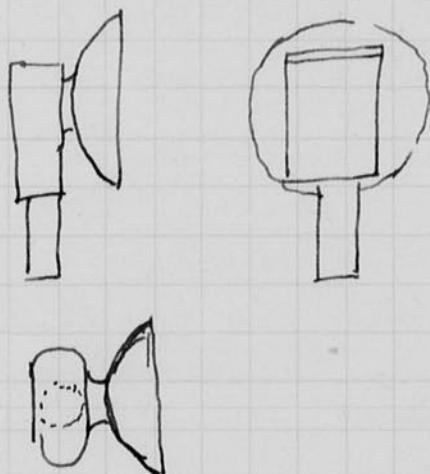

Harold E. Egerton.

Allan Stinson and [unclear] were in on Monday March 14 to discuss portables. They showed me a 10 pound electrolytic unit that had 180 mf at 900 volts.

I showed these men the Red portable that has just been returned from Eastman with a letter from Board showing that they are not interested.

This Red portable contains 80 mf at 950 volts. The flash tube is a 1 1/2 turn spiral pushed out from the reflector to give flat coverage. The light is about 3/4 that of the old Kodatim.

The dry battery unit to operate this unit operates from a 7 1/2 volt 8 pound ~~unit~~ battery. On this is a vibrator and transformer.

Vibrator transformer. ordered from Mystic.

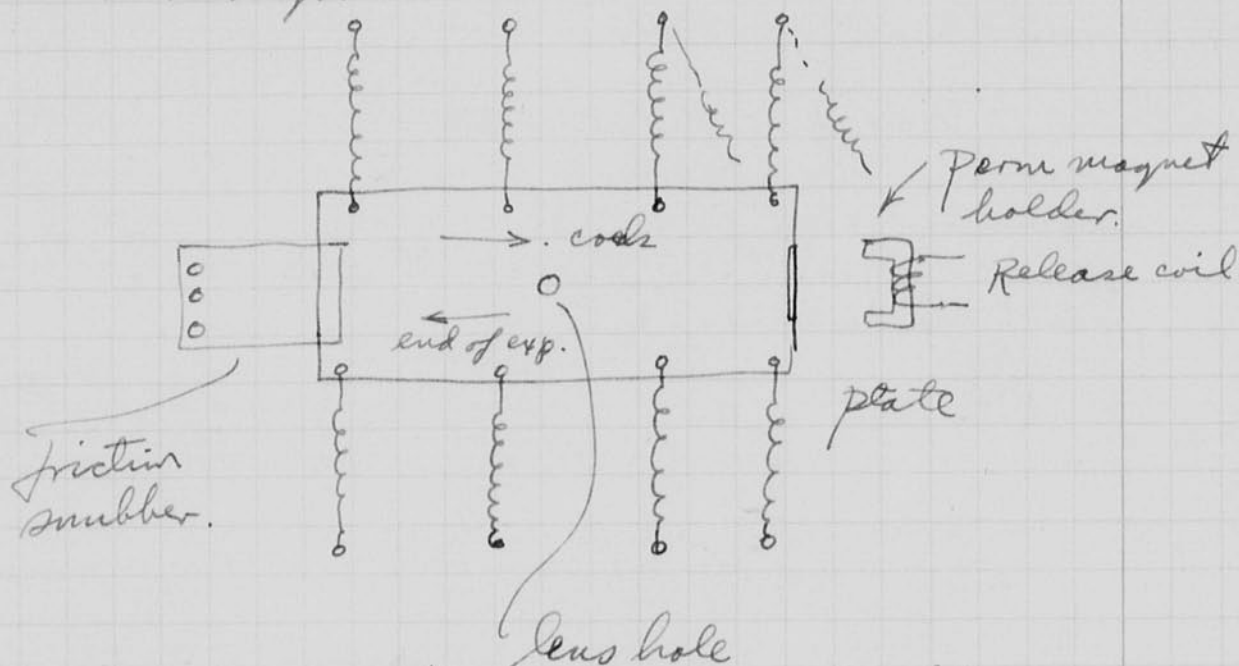

Power supply to operate the Red flash unit from a 2 volt D.C. Wet battery.

Primary 60 turns #14 or 16 with C.T.

Secondary 2220 turns # 32.

Mar 18 1949 #222.

Shutter design

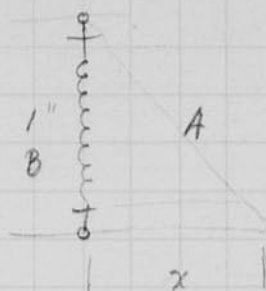

The plate is spring suspended. It overshoots and is held by the friction snubber at the end of the stroke.

focus adjustment of lens board.

Mar 21 1949

David E. Egerton.

.600 μ F / 100 V.
FT-220.

The Polaroid co have had the two light electrolytic flash unit for several months on trial to gain experience with electronic flash.

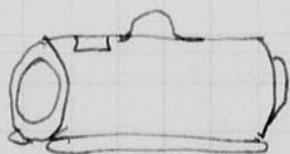

Their Polaroid camera has a sync connection for 15 ms lead time. There is no provision for instantaneous sync. (X)

Gemeshausen and I went to the Polaroid plant on Thursday March 17 and discussed flash units. Present Resembler Fairbanks. Matz,

Gemeshausen offered to put in a 2D-21 thyristor time delay circuit for the shutter sync. This probably will work since the shutter contacts are closed and remain closed. Furthermore the shutter part always moves at the same initial velocity. A sample ^{shutter} will be given to us for experimentation.

We discussed the form of the flash unit. I suggested a slidable pack that would slide along on the floor behind the photo grid. I had used this unit that way at the E. G. S. banquet in the Kurume Hotel.

New form

FT-220 on both ends.

controls

Matz also asked us to consider ways of cooperation on V.V. lights for a microscope project that Polaroid is working on. We plan to see him and others at Polaroid this afternoon so the work can be started.

March 21, 1949.

Harold Edgerton

We had a conference at Polaroid with Land, Matz and McCune. Gemmeshausen and I were there to discuss the application of flash tubes to the ultraviolet microscope that is being developed for the American Cancer Society.

The scheme seems to be to use several lamps with a grating so that the lamp acts as a slit. The exposure and energy is under control by the voltage and capacity.

At present the method is to use a moving grating or a series of filters.

A series of lamps were left with Matz to test with flash equipment.

Transformer design see p 65

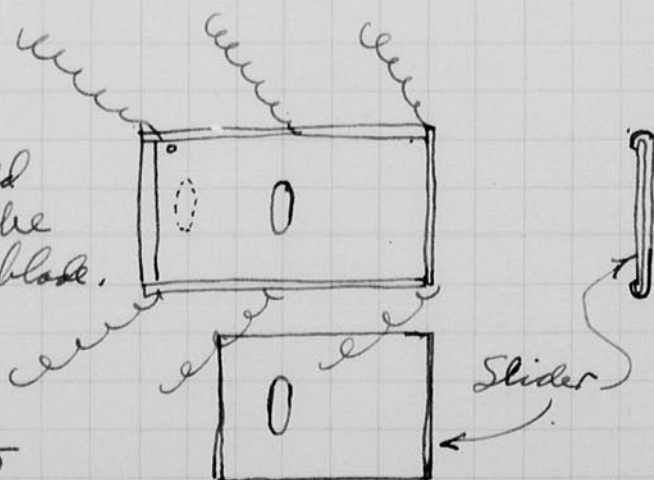

for 600 mf 1000 volt capacitor with integration delay circuit

15/16" square plate.

Shutter design

The slider is held against a stop on the back of the shutter blade. When the plate is snapped back by the spring the cover plate slides to the closed position.

April 1, 1949

Howard Edgerton

Color Photography of Boston Garden
 Churchill speech. March 31 1949.

Two 10,000 watt second units, with FT-17A tubes, were used for all illumination. Both were in 30" reflectors at 80 ft from the speakers stand.

The camera was in the center side entrance at the stadium level. Another camera 4x5 was located at the center entrance near the front row of boxes.

Dore Nilsey shot some color in the 4x5. I used Kodachrome daylight 4x5 with a cc 15 filter. The aperture was f 4.7 for most shots with a few at f 5.6.

The light meter showed about 50 $\frac{15}{\text{sq ft}}$ at the podium for each lamp.

We also had a 3000 WS in a beamed reflector directly over head 6.5' up.

Spiral lamp.
1000 f.p.s.
by oscillator

Positive film
f 1.5?

Shutter is composed of two
overlapping discs that
rotate together by a linkage.

angle is about 10 degrees. (12)

active time of shutter corresponds to time required to travel through this angle.

$$1/T = \frac{37.2}{12} = .31 \text{ } \frac{1}{\text{ms}} \text{ exposure.}$$

$$T = .322 \text{ ms.}$$

$$T_{\text{eff}} = .161 \text{ or } \frac{1}{6200} \text{ sec.}$$

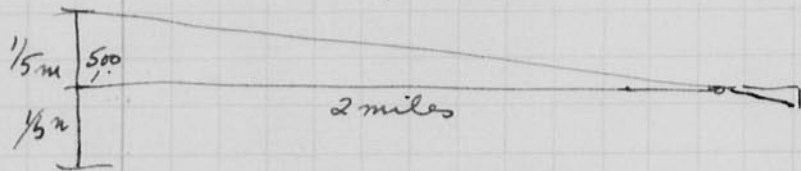

Angular Resolving power
of a circular aperture.

$$\text{angles} = 1.22 \lambda / d \quad \lambda = 5000 \text{ \AA} \quad 5'' \text{ arc/diana}$$

$$= 1.22$$

$$\lambda \text{ for } 5000 \text{ \AA} = 5000 \times 10^{-10} \text{ cm.}$$

5'' lens required.

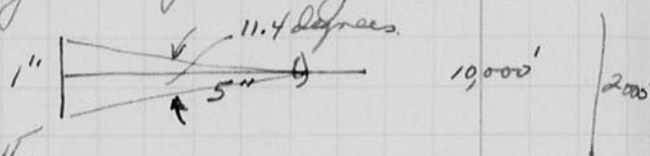

$$\frac{2}{5} = \frac{2}{10} \text{ radians}$$

$$\frac{2}{10} \times \frac{360}{2\pi} = \frac{72}{2\pi} = 11.4 \text{ degrees}$$

$$5'' \times \frac{2}{10} = 1 \text{ inch field at focus of image.}$$

$$\text{angle} = 2 \times \tan^{-1} \frac{.5}{5} = 2 \times 5.7^\circ = 11.4 \text{ degrees.}$$

June 8 1949 A.S.E.

Saw A.M.I.
Experiments by Carlson to show how
much continuous light is required to
wipe out flicker of 24 cycle stroboscope.

Continuous light.

33,000 lumen source tungsten
Reflector $M = 10$

$$L = \frac{33000}{10} \times \frac{M}{d^2} = 330 \text{ lumens/sq ft.} \\ = 3300 \text{ ft candles.}$$

Flash source

50 mf 2000 V

100 watt sec.

$$\text{lumen sec} = 1200$$

$$\text{h cps} = 120.$$

$$\text{h cp} = 120 \times 24 = 2880$$

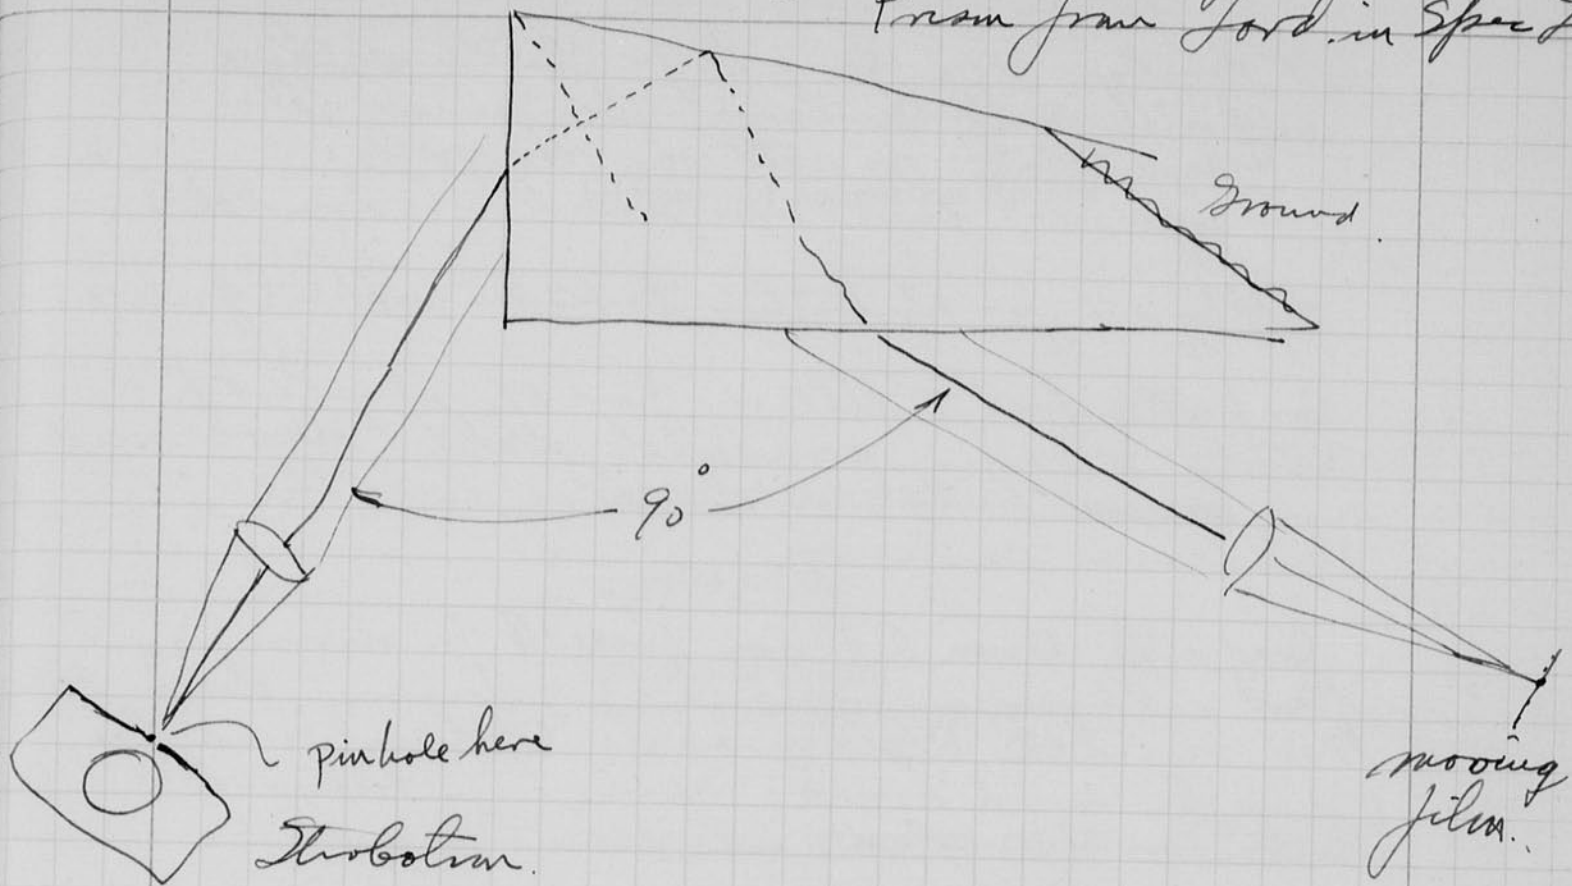

$$L = \frac{2880}{10^2} = 28.8 \text{ lumens/sq ft} \\ = 28.8 \text{ ft candles.}$$

thus the continuous light is
about 12 times the strob light for elimination
of flicker.

For proper color balance the ratio
should be about 2 to 1. or 1 to 1.

Photos of the moon during eclipses.

July 7, 1949. I spent June 29 in the mesocope plant in Freehold N.J. with John Sluder. microflash photographs were taken of the spraying process.

met Joe Costa at 6 pm and went to Long Island to his home. then we went to the Roosevelt Race way to set up the lights for the horses. Photos were taken June 30 July 1, 2 and 4. Those who helped Norman McRoberts, Milton Schwartz, Sam Carlson, etc.

^{Monday} July 18, 1949. Matz of Polaroid called Friday to report that the restricted arc tube ~~is~~ is no better than the straight tube. It wants a factor of several hundred over that now available.

Sluder is due today to discuss Mesocope photos taken on June 29.

July 19, 1949

H.C.

Tom Sinclair called from G.R. on July 15
to notify me that G.R. was not interested
in the 60 cycle strobe scope that I left with
them a month or so ago.

 Small Ejector.

Inspected the composing unit with
 Caldwell yesterday at Charles St in
 Cambridge. Two French workers ran the
 unit so that I could see it operate.

A Sylvania tube is used for
 light, excited from a 1mf 500 volt
 capacitor. An OAS is used for a
 trigger. Photo cell amp combination
 synchronizes the light flash for registration.
 The wheel with the type goes at 600 rpm.
 The max flashing rate is 20 per sec.

START OF AN ATOMIC EXPLOSION is depicted in these photos, released yester-
 day by the Atomic Energy Commission. At left, the chain reaction begins in an en-
 closure atop a steel tower at test area in Nevada. Second photo, made about one-millionth
 of a second later, shows fireball enveloping the enclosure. Each picture represents
 activity of less than one-millionth of a second. Atomic blast was photographed last
 Autumn by Edgerton, Gernsmaen & Grier, Inc., of Las Vegas, Nev., and Boston.

See MacRobert's note book for further tests.

Our "Red Flash" unit with 82 mf 950 volts was tested by Eastman Kodak several months ago and given the "no" because of its lack of light for color. We found a guide number of 12 with daylight Kodachrome. The Red Flash has a beam c.p. sec. output of 800. Capacitors used are Sprague 165 mf rated 475 volts. Lamp - $1\frac{1}{2}$ turn spiral.

The G.E. Co have sent out samples of a V shaped tube capable of 100 w.s. at 1000 volts. We have tried this tube with the sample reflector as furnished by G.E. and find the efficiency is comparable with the $1\frac{1}{2}$ turn tube above.

Our present thinking calls for the following performance.

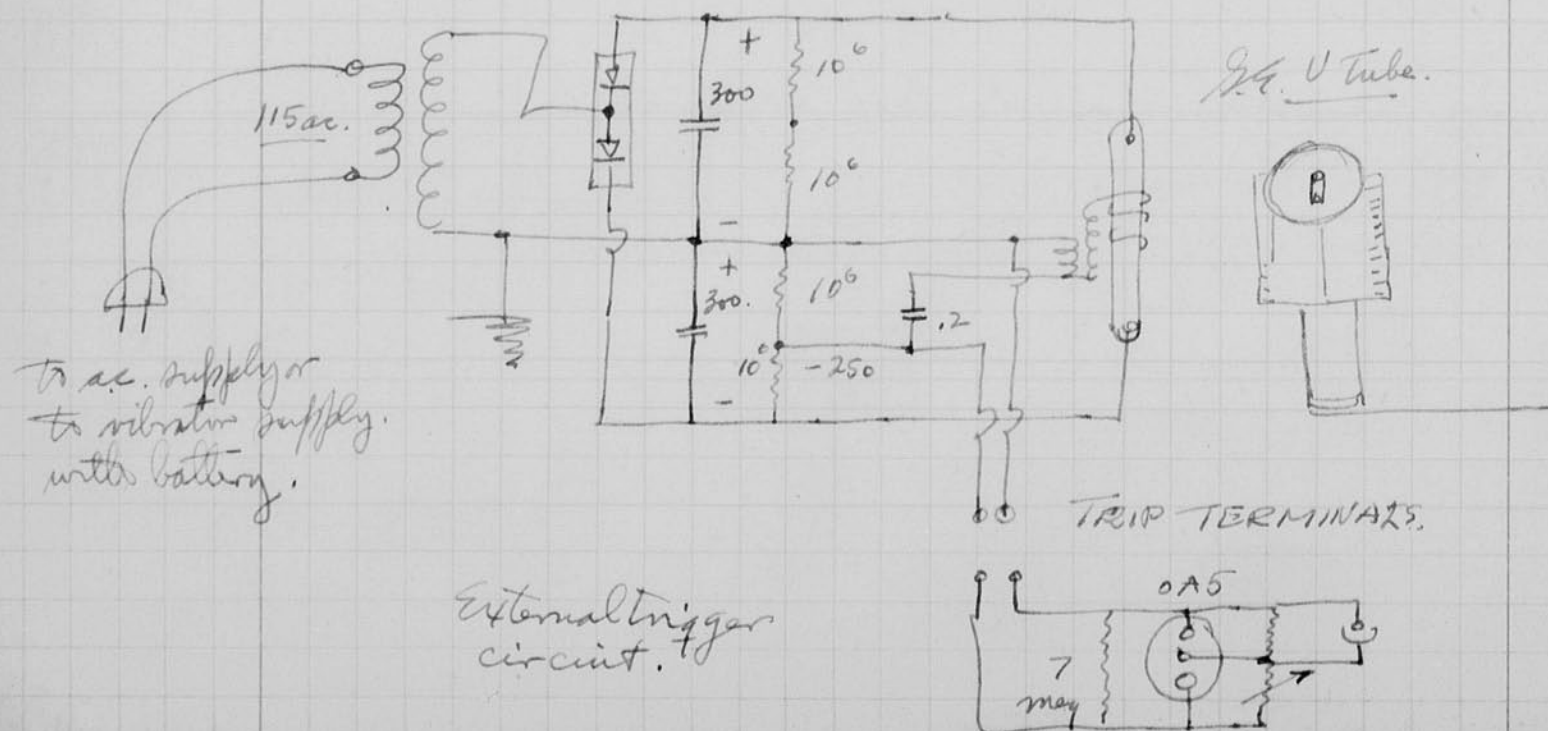

Capacity 150 mf 900 volt

(2 300 mf 450 volt mallyon in series). cost \$1.70 in 1000 lots.

Output 960 V. 1600 bc.p.s. on axis.

Angular distribution satisfactory. The color (daylight Kodachrome) guide No should be about 20 with 35 mm film.

Hartford M.I.T. Club with Don Severns several weeks ago.

Pittsburgh - Mellon Inst. - Gaseous Conduction meeting
 Prof. Bill Allis. - Talk on Speed photos.

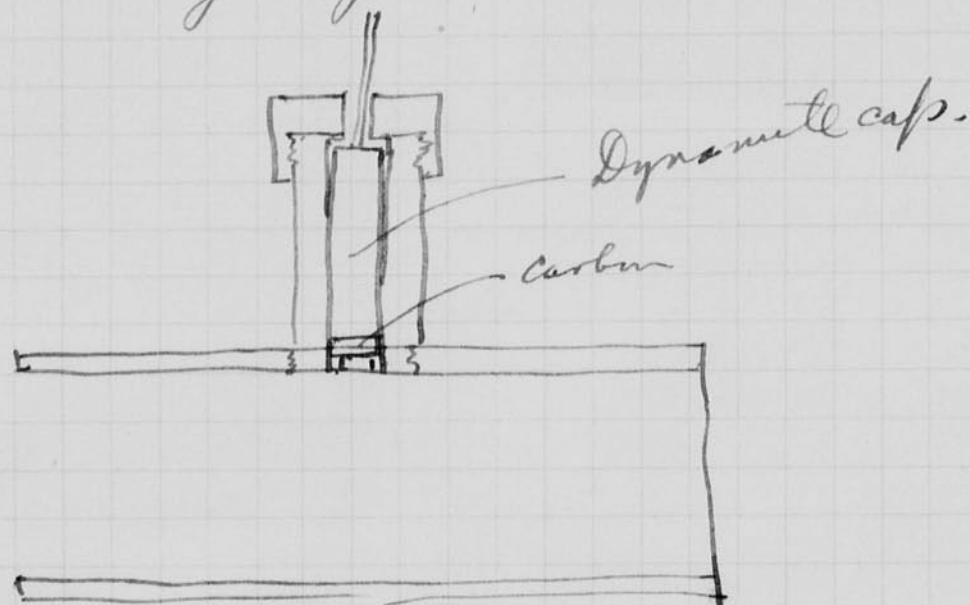

M.I.T. R.L.E. conference talk Nov 15 1949 Tuesday.
 Visiting committee from Washington D.C.

Nov. 22, 1949.

H. E. Edgerton.

Discussed fast closing shutter with Herb Sier yesterday afternoon. He told me of the "explosive behind a mirror" as used with the Bowen camera.

It seems as though smoke could be blown into a tube to obscure the beam. I suggest a pipe in the path with dynamite caps in the sides to blow material into smoke. Fussell suggested graphite, or compressed carbon black as material that would disperse into fine particles.

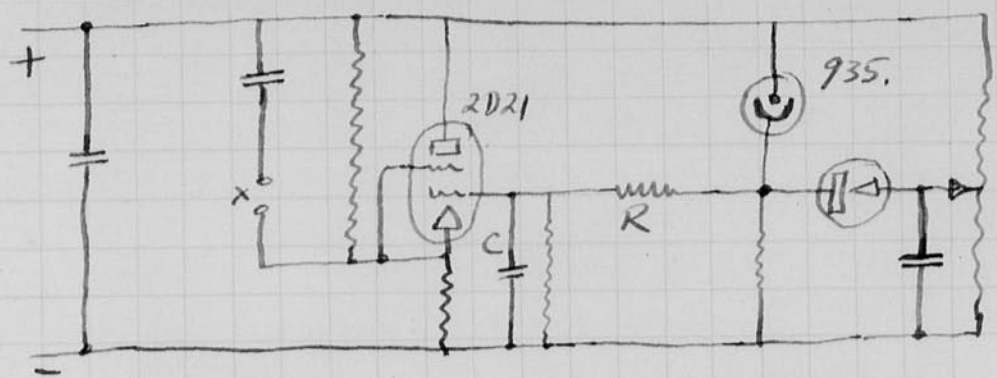

a cloud of material will proceed from the end of the caps into the cylinder at a high velocity which may be as much as 5000 ft per second. two clouds will meet and disperse obstructing the optical path.

Herb called on the phone this morning. He is going to design a test structure for the experiment.

cont.

Photoall trip with time delay.

 Diode limiter holds upper value
 of voltage on delay circuit.

RC network sets delay time on
 firing potential of 2D 21 thyristor.

this system depends upon the light
 holding its high value until the delay
 network trips.

Nov 28, 1949. Discussed system of heating grid
 wire with condenser discharge to make
 smoke in a glass cell with fused on the
 plume or Nov 25. He said James Vanman
 had suggested a parallel grid system
 of wires to explode.

This wire system could be wound on
 a glass form as shown below

wind with small wire
 Put cover glass on the sides
 and find up.

Nov 29, 1949.

H. J. Dwyer

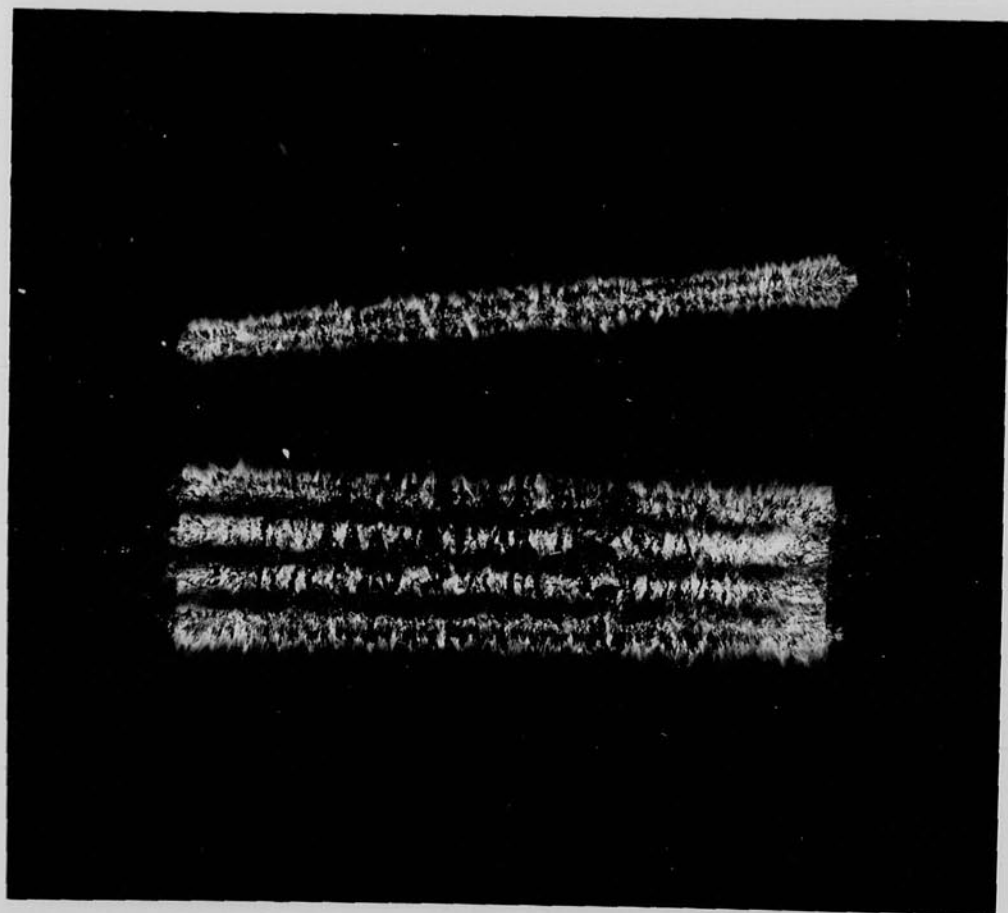

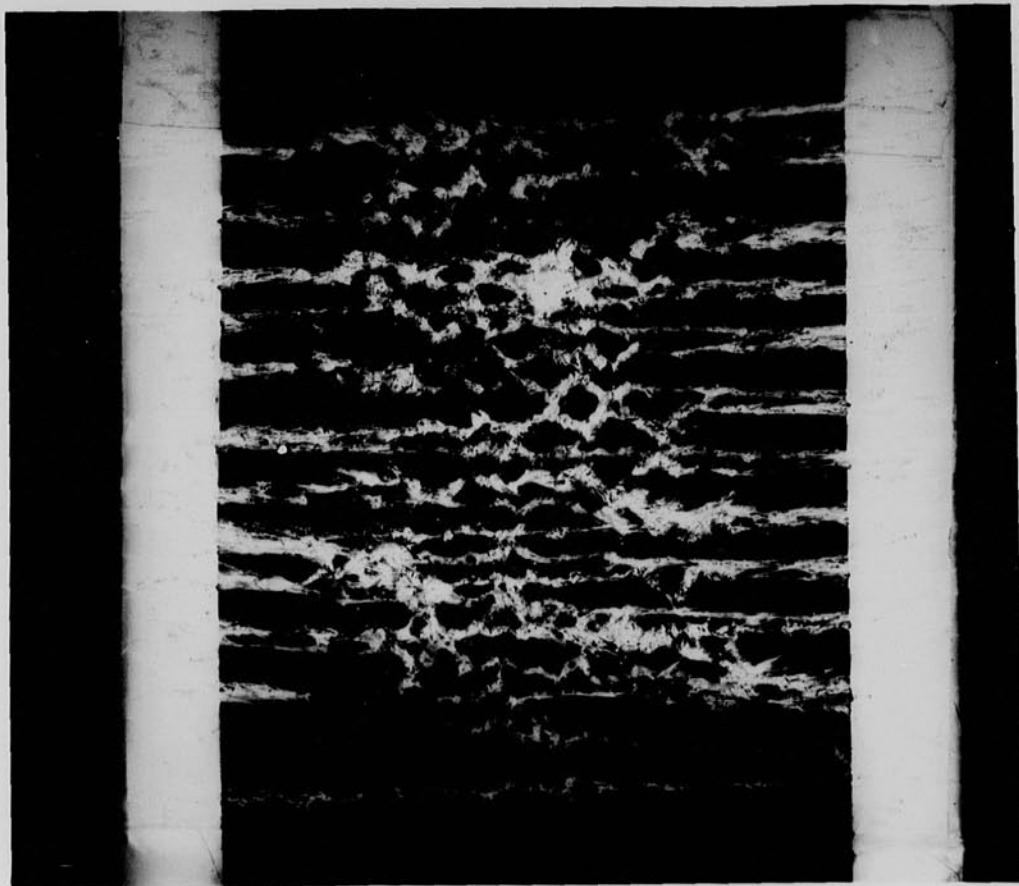

Gave talk at Grad. House last night to M.I.T. Alumni Council. Wilkins and Taylor brought over the magnetic contactor. Lew Rosenblum brought over a Polaroid camera. Demonstrations and slides were shown.

Shutter experiment with exploding wires, copper enamel coated show a poor pattern due to enamel breaking off in flakes.

Tried 3 glass construction today the first slide had about 20 strands of nichrome .0031" 67 ohms per foot. 76 mf at 2000 volts with a series gap caused the wire to melt but not completely evaporate.

a second example with ten strands of .0031 nichrome was shot with 76 mf at 2500 volts. One of the end side glasses blew up. The metal film was not very dense. The metal was spread over a width of about $\frac{1}{8}$ of an inch but irregular.

Next 10 strands of .0056 with 100 mf 2500v. Both core glasses blew up. Wyckoff says $\frac{1}{4}$ of a percent transmission

X 100

X 1000

No light in

27C¹ also 10 cps or 1 cycle = 100 μ sec.

27E

Tried one shutter with the stroboscopic light at the same time with the following results.

down 10:1 at 75 μ sec.

down 100:1 at 125 μ sec.

never gets down to 1000:1 on screen.

27D¹
27E¹

Tried two shutters with stroboscopic light off so the only light is the light from the gluing of the wires. Results:

down 10:1 at 50 μ sec

down 100:1 at 100 μ sec

down 1000:1 at 200 μ sec. N

27F¹
27F²

Tried two shutters to determine if the condenser-shutter circuit was oscillating and keeping the light on. Results.

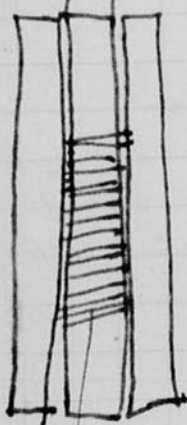

oscillates for 50 μ sec

Might need damping if we can get light down to a reasonable length.

Tried one with 100:1 attenuator between the shutter & the cell. Light came on at 25 μ sec after gap fired and light was down to zero at 45 μ sec.

Note
No wood blocks used
here or as in pg 137
shutter as in following
sketch.
#27A
nickel conductor

circles
taped together

22 strand #.005 lead
1400V 45 μ f.

X100 filter over P.C.

no result. light is - no light

26 strand .005" lead wire

1500 V. 45 μ f.

no filter over photo cell.

Result.

Light output small - goes up and comes
down to \approx the base line in 15 μ sec. - Density
of shutter = X 200

#27B

14 strand .005 lead wire

1350 volts. 45 μ f

No filter over photo cell

Result: higher light output; density

#27C
filter \approx 200

14 strands 0.011" lead? first wire
did not fire at 1400V.

7 strands of 0.011" first wire
fired at 1800V.

#27D
look good as a shutter
No film, but it didn't

26 strands 0.005" lead wire as
shutter.

1400V. 45 μ f

Cap fired late - no result.

decreased gas spacing

12-21-49

#27E

26 strands 005" lead wire
 1400 volts 45 μ f
 Low density deposit with holes.
 took picture to determine how it would be
 as a shutter. - Gap fired late
 No result.

#27F

36 strands .005" lead wire
 2000 volts 45 μ f.
 dense deposit (black) with some small
 globules of metal (silvery) left on glass.
 as a shutter - it closed to $\frac{1}{10}$ light in 50 μ sec.
 $\frac{1}{100}$ light 110 μ sec
 $\frac{1}{1000}$ light 165 μ sec.

~~starts~~ after the stroboscopic light went off. We
 cannot tell where the gap fired. but from experience
 it should have fired about 50 μ sec after light came on.

#27G

40 strands .005 lead wire
 2150 volts 45 μ f
 X100 filter between shutter + photocell.
 Light follows calibration curve up to where shutter
 begins to cut off (20 μ sec after gap fires) and comes down
 to the X1000 curve 50 μ sec after gap fires. No readable
 after that. There is good indication that the light
 from the shutter is negligible compared to that from
 the stroboscopic light source.

#27H

Construction changed
 Use 1 thin .038" ^{2x2} film slide glass for center piece
 Use 0008 mil aluminum foil doubled to conduct current to
 wires. 0.005" lead wire and 2 film slide plates
 on each side.

40 strands 0.005" lead wire
 2200 V 45 μ f
 X10 filter between shutter & photocell
 density about 100.
 follows the 10:1 density calibration curve
 up and begins to close 20 μ sec after gap
 fires.

12-21-49

#28A

Fixed two shutters described bottom page
137 at 2400 volts 45 μ f

$\frac{7}{8}$ " filter
40 strands 1.005" lead wire
both get down 100" in less than 50 μ sec.
On drops off about 300" almost in a period of

H.B. Edgerton
M.I.T. Jan 30 1950

Feb 2 1950

Howard E. Egerton

Rapatrionic shutter design.
 Conf at 160 Brookline ave yesterday on
 the shutter. It was decided to use
 2 slugs of glass and 3 polaroid sheets.

Conditions for shutter.

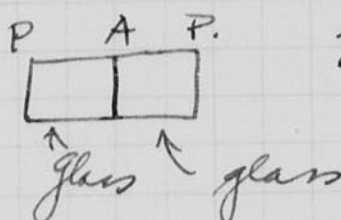

$$C = 1.5 \text{ mf } 5 \text{ KV}$$

$$L = 3 \text{ } \mu\text{h.}$$

$$f = 80,000 \text{ kc.}$$

$$T = 12 \text{ } \mu\text{s.}$$

$$\text{Energy stored} = \frac{CE^2}{2} \text{ in capacitor}$$

$$T = 2\pi\sqrt{LC} \text{ seconds.}$$

If the electrostatic energy all goes
 into the magnetic field, then $\frac{CE^2}{2}$ should
 be constant for a given type.

$$T = 2\pi\sqrt{LC}$$

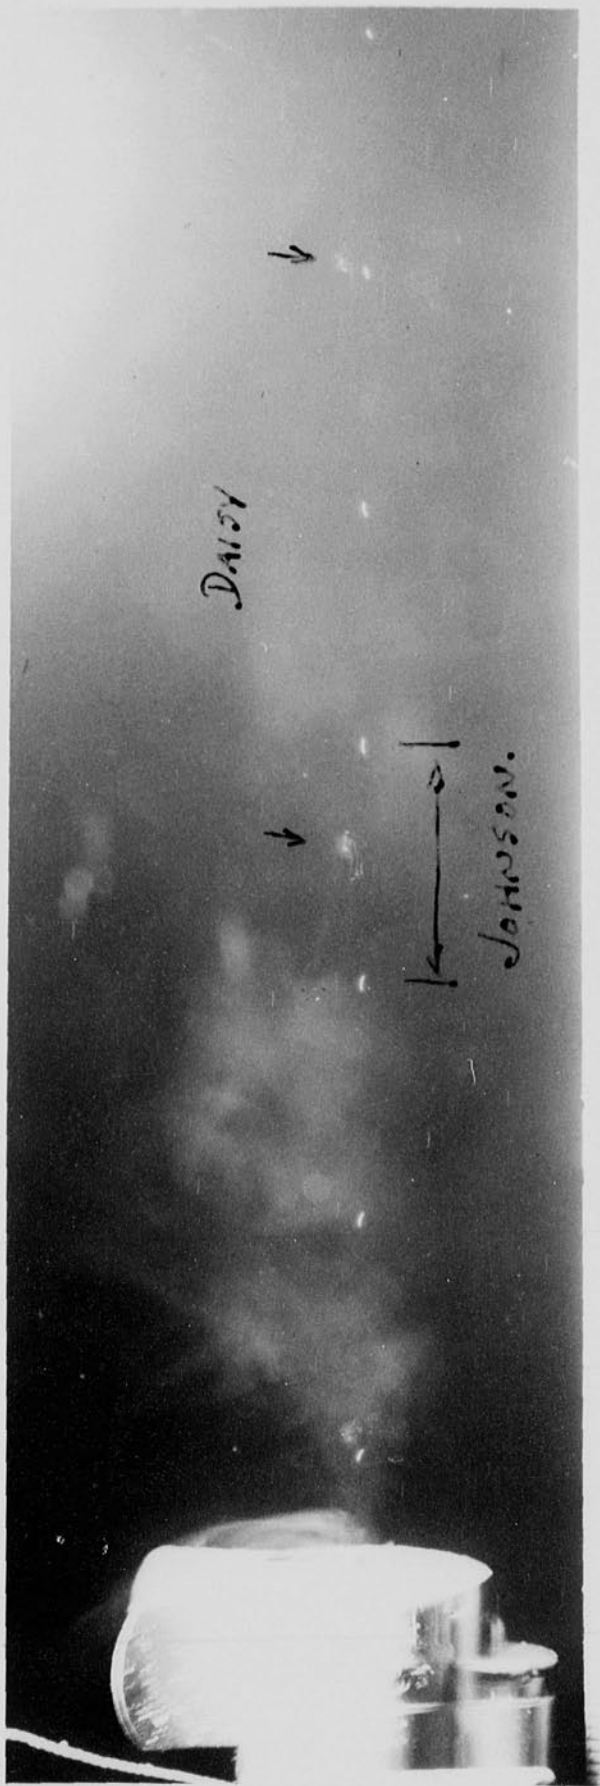

$$\text{and } \frac{CE^2}{2} = K \text{ a constant.}$$

$$C = \frac{2K}{E^2}$$

$$T = 2\pi\sqrt{L \frac{2K}{E^2}}$$

$$= \frac{2\pi}{E} \sqrt{L2K}$$

Therefore the duration is inversely proportional
 to the voltage of the capacitor if the energy
 is kept constant.
